15 tests in all are quoted. Amongst these the highest space (approximate) per head in cubic feet was 12,660 and the lowest 2700. The temperature varied from 80° to 97° in no case was it under 80° The number of volumes of carbonic acid per 10 000 varied from 7 6 to 41 3. There is little cause for surprise that the life of a cotton spinner should not as a rule, be a long one. In one or two directions considerable improvements have of late taken place in the factories. It now rarely happens that water contaminated by sewage is used for moistening the air of the workrooms but the practice of using impure water for that purpose was formerly quite a common one. The more general use of electricity for lighting purposes is a great boon At the present time the cotton weaving factories which are lighted by gas in many instances contain air much contaminated by carbonic acid gas. In a table recording the results of 23 examinations of air from such factories the amount of carbonic acid gas was found to vary from 13 2 to 41 7 volumes per 10 000 volumes. It seems very remarkable that the floor of a weaving shed is as a rule never washed. It is less a matter for surprise that "spitting on the floors is by no means unknown among weavers" and we have the official assurance that this is the case The general filthiness of many of the weaving sheds may be fairly well gauged from the following gratulatory paragraph from the report "There are says Mr Williams, "I am glad to report, a few sheds in Lancashire where the floors, except immediately under the looms, are washed weekly and the result is so extremely pleasing that it is to be hoped that the practice will extend to other sheds. The inspector of cotton cloth factories has done an enormous amount of useful work, but it is evident that more remains behind

THE COUNTY OF DURHAM MEDICAL UNION

THE fourth annual meeting of this union was held in the Town Hall, Durham on June 23rd Dr E. JEPSON J P (Durham), the President being in the chair There was a large attendance of members amongst those present being Dr James Murphy (Sunderland) the Vice President Mr E. H Davies (West Hartlepool) Mr J Arthur (Wingate),

---

[4] "The arrangements for ventilation shall be such that during working hours in no part of the cotton cloth factory shall the proportion of carbonic acid (carbon dioxide) in the air be greater than nine volumes of carbonic acid to every 10,000 volumes of air."

[5] THE LANCET Oct. 26th, 1901, p. 1146

[6] The samples were taken from the breathing level and near to the centre of the shed in each case

[7] THE LANCET Oct 26th 1901 p. 1147

between them being occupied by a kind of ligamentous union of much consistency Should any inconvenience remain, it can be easily obviated by a simple artificial contrivance. It is to be hoped that a full and accurate detail of so interesting an operation will be speedily published but even this slight notice may lead to its immediate adoption in many cases which are perhaps at this moment consigned to an hopeless fate

A similar operation was performed on Friday last, with the most complete success by Mr CUSACK, Surgeon to Stevens's Hospital, who removed a still more extensive portion of the maxillary bone with a tumour several inches in circumference. T

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

of the largest English towns 9112 births and 4123 were registered during the week ending July 19th. ual rate of mortality in these towns, which had 1 15 4 and 14 3 per 1000 in the three preceding ncreased again last week to 14 5 per 1000 In London h rate was 14 1 per 1000 while it averaged 14 6 in other large towns. The lowest death rates in these were 5 5 in Hornsey 5 6 in Handsworth, 6 7 in stow 6 8 in Newport (Mon.) 6 9 in Willesden 7 7 Norton, 8 1 in Great Yarmouth, and 8 6 in Aston o highest rates were 18 2 in Liverpool 18 5 ster 18 8 in Stockport, 21 4 in Rhondda ockton on-Tees, and 25 9 in Merthyr Tydfil deaths in these towns last week included were referred to the principal infectious nst 522 and 533 in the two preceding weeks deaths 129 resulted from measles, 119 -cough, 117 from diarrhœa, 64 from diph n scarlet fever 43 from fever (prin and 27 from small pox. No death from ases was registered last week in Hornsey astings, Great Yarmouth Devonport Preston in the other towns they caused rtional mortality in Portsmouth Plymouth -on Tees, Gateshead, Rhondda, Merthyr The highest death rates from measles outh, Reading West Bromwich Bury l, Stockton-on Tees and Rhondda from teshead from diphtheria in Tottenham whooping-cough in Leyton Portsmouth, y Smethwick, Grimsby, and Barrow in ver in Ipswich Stockton-on Tees and d from diarrhœa in Plymouth Hanley otle, Rotherham and Middlesbrough The ll pox registered last week included 16 ondon, eight to Swansea, three to Gates ootle. The Metropolitan Asylums hos 59 small pox patients on Saturday numbers declining from 1615 to 579 on Saturdays 48 new cases were admitted against 129 58, and 51 in the three pre- The number of scarlet fever patients in these the London Fever Hospital which had been 2352 at the end of the three preceding weeks, n to 2377 at the end of last week 332 new dmitted during the week, against 276, 255, the three preceding weeks. The deaths referred of the respiratory organs in London which 194 168 and 159 in the three preceding weeks declined last week to 155 and were 11 below the d average The causes of 50 or 1 2 per cent, deaths in the 76 large towns were not certified by a registered medical practitioner or by a coroner he causes of death were duly certified in Portsmouth ol Leicester Nottingham Salford, Leeds Newcastle, in 46 other smaller towns the largest proportions of ertified deaths were registered in Birmingham Liverpool Helen s Warrington, and Hull

HEALTH OF SCOTCH TOWNS.

annual rate of mortality in the eight Scotch towns had been 16 3 and 16 2 per 1000 in the two preceding further declined to 14 7 per 1000 during the week July 19th, but showed an excess of 0 2 per 1000 the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13 2 in Leith and 13 6 in Greenock to 15 3 in Edinburgh and 20 2 in Dundee. The 475 deaths in these towns included 15 from measles, 15 from whooping-cough 13 from diarrhœa, and one from scarlet fever but not one from either small pox, diphtheria, or "fever" In all 44 deaths resulted from these principal infectious diseases last week, against 66 and 62 in the two preceding weeks. These 44 deaths were equal to an annual rate of 1 4 per 1000 which was 0 6 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles which had been 15 13, and 22 in the three preceding weeks declined again last week to 15 of which seven occurred in Edinburgh, four in Glasgow, and two in Dundee. The deaths from whooping cough, which had been 14 16 and 14 in the three preceding weeks, rose again to 15 last week and included seven in Glasgow three in Dundee three in Edinburgh, and two in Aberdeen. The fatal cases of diarrhœa, which had been 16, 24 and 15 in the three preceding weeks, further declined last week to 13, of which six were registered in Glasgow two in Edinburgh two in Dundee, and two in Aberdeen The deaths referred to diseases of the respiratory organs in these towns, which had been 101, 87 and 74 in the three preceding weeks, further decreased to 62 last week, and were 17 below the number in the corresponding period of last year The causes of 25 or more than 5 per cent of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin which had been 19 1 and 16 9 per 1000 in the two preceding weeks, rose again to 20 2 per 1000 during the week ending July 19th During the past four weeks the death rate has averaged 19 0 per 1000 the rates during the same period being 14 5 in London and 17 0 in Edinburgh. The 147 deaths belonging to Dublin registered during the week under notice were 24 in excess of the number in the preceding week, and included 14 which were referred to the principal infectious diseases, against nine, 11 and 17 in the three preceding weeks, of these eight resulted from measles, four from fever one from diphtheria, one from diarrhœa, and not one from either small pox scarlet fever or whooping-cough These 14 deaths were equal to an annual rate of 1 9 per 1000 the death rates last week from the same diseases being 2 2 in London and 1 9 in Edinburgh. The fatal cases of measles, which had been six in each of the two preceding weeks increased last week to eight, the four deaths referred to fever corresponded with the number in the preceding week while the mortality from diarrhœa showed a decline The 147 deaths in Dublin last week included 16 of children under one year of age and 31 of persons aged upwards of 60 years, the deaths of infants were slightly below the number in the previous week while those of elderly persons showed a slight excess Eight inquest cases and two deaths from violence were registered and 69 or nearly one-half of the deaths occurred in public institutions. The causes of four or nearly 3 per cent of the deaths registered in Dublin last week were not certified.

THE SERVICES

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified —Fleet Surgeon W Eames to the *President* additional for three months course of hospital study Staff Surgeons G Howlett to the *President* additional, for three months course of hospital study E. St. M Nepean to the *Æolus* and F J Burns to the *Royal Sovereign*

ARMY MEDICAL STAFF

Colonel James A. Clery C.B. R A M C. to be Surgeon General vice A F Preston retired. Dated May 23rd 1902.

ROYAL ARMY MEDICAL CORPS.

1st Life Guards

The appointment of Major Nicholas C. Ferguson, C.M.G from the Royal Army Medical Corps to be Surgeon Major which was notified in the *London Gazette* of Feb. 14th 1902, is cancelled

Major Benjamin William Chatterton Deeble, from the Royal Army Medical Corps, to be Surgeon Major Dated July 23rd, 1902.

To be Colonels —Lieutenant-Colonel William G Pratt, on augmentation (dated April 1st, 1902), Lieutenant-Colonel William E Webb, vice J A Clery, promoted (dated May 23rd, 1902

Lieutenant M G Sterling assumes medical charge of the Louise Margaret Hospital District Staff, Army Pay Department, Fire Brigade, Military Police, Army Chaplains' Department, Model School, and Army Veterinary Department not attached to units at Aldershot

ARMY MEDICAL RESERVE OF OFFICERS

Surgeon Major E L Freer to be Surgeon-Lieutenant-Colonel

MENTIONED IN DESPATCHES

In a despatch from Lord Kitchener, dated Pretoria, June 1st, to the Secretary of State for War, the following names are mentioned —

Surgeon Major J A. Devine, Canadian Mounted Rifles, for good service in the action at Boschbult on March 31st

Civil Surgeon A. L Hoops who, in the same action, was four times wounded, and when no longer able to move about refused to be taken to the rear and remained in the firing line giving directions for the treatment of other wounded men

Lieutenant T F Ritchie, R.A.M.C, for valuable work in the action at Holspruit on April 1st.

Civil Surgeon R F Williams, R.A.M C, for gallantry in action at Moolmanspruit on April 20th

Serjeant E Haynes, R.A M C, is mentioned for gallantry under heavy fire at close range, on Jan 29th, at Sweethome, Orange River Colony

THE MEDICAL STAFF COLLEGE

It is understood that, pending the erection of permanent buildings, the War Office authorities have made temporary arrangements for renting some of the laboratories of the Royal Colleges on the Thames Embankment. There was, we believe, some talk of the new military hospital for the Guards near the Tate Gallery being utilised for the purpose of clinical instruction, but it is questionable whether the site as a substitute for Netley would prove sufficiently large, and in any case provision would have to be made for the study of tropical diseases We think it would be quite possible to institute some general arrangements whereby the medical schools and hospitals and post-graduate courses of instruction in London could be made available for army medical officers and candidates As regards tropical diseases there are usually a large number and variety of cases of this kind in the Royal Victoria Hospital at Netley, and, for the present at any rate, it might also be possible to arrange for the army medical candidates to spend a portion of their course of instruction there

A VISIT OF INDIAN TROOPS TO THE HOUSE OF COMMONS

Medical officers who have served in India and have been brought in contact with Indian troops must have noticed that they very commonly and naturally, as it were, comport themselves in a dignified, respectful, and fitting way when any occasion calls upon them to do so A little incident at the House of Commons the other day was a case in point A detachment of Bengal Lancers in their handsome uniform paid a visit to the House on July 21st and arrived there just before the time of its sitting As the Speaker's procession passed through the lobby of the House the soldiers stood at attention and saluted in military fashion the mace and Speaker as they passed The situation was both picturesque and effective as well as a spontaneous exhibition of respect and good manners such as are not always manifested by people in this country

A NEW FORM OF FIELD EQUIPMENT FOR GERMAN MILITARY SURGEONS

According to the *Deutsche Militärarzt Zeitschrift* for January last a new equipment for army medical officers has been devised and sanctioned It consists of a black leather satchel lined with canvas and fitted with pockets for the reception of instruments, medicines, and dressing material The outside case measures about 9 by 7 by 1 5 inches, and in shape resembles an enlarged card holder To keep it in position on a level with the lower border of the tunic there is a strap which is to be worn beneath that garment. Notwithstanding its small dimensions the satchel contains all the customary instruments, with the exceptions of a percussio hammer, a pleximeter, and a magnifying lens The pric fitted satchel, is said to be about 12*s*

THE CANADIAN RED CROSS SOCIETY

A tastefully printed report of the Canadian branch of t British National Society for Aid to the Sick and Wounded War has just been issued Captain Charles A. Hodgett A.M S, the honorary secretary, in a letter dated Toront April 30th, 1902, gives an epitome of the society's wor stating that after a careful review of letters and reports the possession of the society he has computed the value the contributions in kind received by the central council ar the several local branches, as well as those forwarded municipalities and private citizens to South Africa throug Red Cross channels, to be $23,552 75, while the total ca receipts of council and branches were $58,826 64, making t total cash value of the society's work $82,379 39

RECRUITING

Now that the war is over and the popular enthusiasm th it excited among the recruiting classes has ceased we sha be better enabled to judge as to what will be the annu average number of recruits joining the army under ordina circumstances We have always thought, and have oft said, that the army authorities would do better by makin their recruiting offices far more attractive looking and placing them in main streets and thoroughfares instead locating them in back streets and out-of the way sites

ROYAL VICTORIA HOSPITAL, NETLEY

Surgeon General G J H. Evatt, P M O, 2nd Army Corp has been appointed the president, and Surgeon General Townsend, C B, C M G, and Colonel M E R Rainsfor C B, members, of a board ordered to assemble at the Roy Victoria Hospital, Netley, to consider and to report as to wh steps should be taken to decentralise the custody of hospit equipment and stores and to consider the best method accounting for hospital diets at that institution

THE SEWAGE WORKS IN THE ALDERSHOT DISTRICT

Lieutenant-Colonel Alfred S Jones, V C, A M I C E has been appointed manager of all sewage works in t Aldershot district by the Secretary of State for War, whic may be taken as a proof that the authorities are well satisfie with the results of his past seven years' work on the restoration and management of the Camp Farm and its Sandhur branch

Correspondence.

"Audi alteram partem"

INSANITY AND THE DEATH PENALTY

To the Editors of THE LANCET

SIRS,—The perusal of your annotation in THE LANCET o July 19th, p 165, on Insanity and the Death Penalty brings to my mind that on various occasions in print, and very constantly for many years as a teacher of medicine, I have insiste on one point too often overlooked or thoughtlessly pervorte —viz, that "insanity," *per se* is not (as we medical me observe it in nature and fact) a definite state which oug either to absolve a man completely from moral responsibilit on the one hand, or on the other to be regarded as consisten with the extreme penalty of the law in a capital offence I regret that I am not at this moment in a physical conditio to permit of a more complete development of this argument but several circumstances have combined of late to lead t an expectation that even a brief communication on the subjec in your columns may at least do some good in quickening th apprehension both of medical and legal experts as regard some of the anomalies referred to in your excellent article on the Dorchester case The case of Musolino the brigand,[1] although we are not yet in possession of the full medico legal details, seems to be an object lesson as to how far the fanatics of the Lombroso school may be expected to go in the way of finding theoretical excuses for flagrant and deliberate, not to say ingrained and habitual, crime At the same time we are receiving from the United States[2], the inquiry, Is Jane Toppan responsible? which means that the law courts of Massachusetts have deliberately excused on the ground of insanity a woman who according to her own confession (which may, however, not be trustworthy), had poisoned over 30 patients under the very eyes of their medical attendants while she was acting as a nurse and reputed in all quarters to be one of the most careful atten tive and sympathising of nurses. In the Dorchester case (Simmons) it is, I think, fairly arguable that there may have been some more or less insane tendencies, or even (as stated) minor epilepsy but that a crime so deliberate, so remorseless and so dangerous to society at large as that of Simmons should not be punished (in a legal sense) at all is (and I agree in this with your correspondent Dr M. Greenwood[2]) a real failure of justice and a practical encouragement to evil doers. In like manner it seems impossible, in the light of average common sense, to maintain that Jane Toppan (whatever she may have been on her own confession sexual per vert or not) was in any just acceptation of the word irresponsible even if the list of her poisonings was to be cut down from 31 to one. To acquit her of 31 murders on this account would be just about as reasonable, from the medical point of view as would have been the holding of Musolino the brigand irresponsible by reason of Lombroso s stigmata, or his theory of the criminel né

---

[1] THE LANCET, June 28th 1902 p 1841.

[2] See Boston Medical and Surgical Journal, July 3rd, p 27

In dealing with the case of Simmons Dr Greenwood writes ' The object of all punishment is to deter I agree but it is apt to be overlooked in these days of refinement and humanitarianism (and I am not to be held as saying any thing against these) that the object of *legal* punishment, as opposed to the vendetta, lynch law or any other less regular form of the *lex talionis* is to satisfy in some measure, the primary and irrepressible instinct of vengeance on the part of society at large. Civilised society, under the influence of Christianity has proclaimed aloud that this irrepressible instinct must be controlled and regulated by law Avenge not yourselves " in the Christain dispensation is the further and logical development of the principle that vengeance belongs to a higher power and that 'the powers that be are ordered by God.' The law accordingly undertakes on the part of society and on the part of that higher power to restrain that primary instinct by dealing equitably, and after full and deliberate inquiry with all causes of offence. But the law can never rightly discharge this great office, either by hanging persons who are manifestly so insane as to be really irresponsible or by refusing to condemn at all persons of the type of Simmons or Jane Toppan. The question of insanity, if raised at all should be treated legally as one of degree and if (as Sir Matthew Hale said long ago) it would be an intolerable outrage to subject to the death penalty a man notoriously and wildly insane it should, on the other hand, be at least possible to give a verdict—*guilty though insane*, with the result of qualifying but not of completely extinguishing the idea of punishment. But to enter now into the difficult question of how this is to be accomplished would carry me too far I will only add therefore, that on the *legal* theory of insanity as a state involving complete irresponsibility, not one of our asylums could be conducted on modern principles If the insane are to be held irresponsible, there is nothing for it but to revert to the old methods of restraint pure and simple but every enlightened man nowadays knows that it is not so.—I am Sirs yours faithfully

Edinburgh July 19th 1902. W T GAIRDNER.

THE CAUSE OF INEQUALITY OF PUPILS IN CASES OF THORACIC ANEURYSM

To the Editors of THE LANCET.

SIRS,—We much regret the apparent misuse of a quota tion from Sir W T Gairdner s article in Allbutt s System of Medicine concerning the inequality of pupils associated with thoracic aneurysm against which he protests The quotation was made from the recent writings of one of the highest authorities on the subject to show what seemed to be the current teaching on this point. On reading that portion of the article again in the light of Sir W T Gairdner s explanation we cannot but feel that there was some excuse for our receiving the impression that he held the view which we ascribed to him

We ought no doubt to have laid greater stress on the cautions which he enjoins to exclude those cases where the inequality is due to causes other than interference with the sympathetic. But we do not gather from the article even now that he supposed that there was any causal relationship between a thoracic aneurysm and anisocoria other than that brought about by paralysis of the sympathetic. We are much gratified to find that Sir W T Gairdner agrees in the main with the observations on which our criticism of the existing theories was based We can only express our deep regret that in our quotation from his work we misrepresented his views upon the subject and trust that he will accept this explanation and apology

We are Sirs yours faithfully

R. CECIL B WALL.
July 19th 1902. E. W A. WALKER.

OBSERVATIONS ON DIET

To the Editors of THE LANCET

SIRS,—Permit me through you to thank Dr Harry Campbell for the tone of his reply in your issue of July 12th to my letter of June 14th especially for the sweet reasonable ness of its general tenour I must also express my gratification for the cognomen procrustean " if it be taken in the pro Boer sense as advocating a good nutritious crust to the aged A sly dig! There is nothing in Dr. Campbell s letter to darken my brow with the angry flush nor mantle my cheek with the shameful blush ' Another!

In his letter taking the first paragraph where he speaks of the vital fires of the aged as smouldering and ' feebly flickering " in support of apparent spare diet generalisa tion may I draw attention to the following If an aged person receives an injury to his tissues do these 'smoulder and flicker"? that is, if surgically treated under antiseptic precautions. Do they act in any way differently, as a general rule, from the tissues of younger persons? Nature supplies the part injured by means of the reactionary reflexes and surgical inflammation (aseptic) with an excess of nutri ment and the tissues at once become young take on embryonic action and the injury heals up right away What is possible in a part I contend is possible to a certain extent in the whole. That is my contention in advocating good full, generous diet. Is not the above mainly a nervous process? And is not the loss of power in the nervous system of the aged the main factor to combat?

In the second paragraph of his letter Dr Campbell states that the healthiest old people are spare eaters." I contend that they are if healthy eating well, and eating for them selves a good full generous" diet as they eat all they want or crave for they certainly do not support the spare diet theory if they do not support the opposite contention.

In the third paragraph Dr Campbell cites certain clinical examples as putting me out of court. I would add to these cases of sarcoma of the upper jaw cancer of the stomach and various conditions of cerebro-spinal degeneration in their last and hopeless stages as equally crushing arguments against the good, full, generous diet." Does Dr Campbell pretend that they are unanswerable contentions for the spare diet" or only for diet *secundum artem* to suit case and condition? The first case of nose-bleeding which he cites might be also hepatic cirrhotic or hepatic diabetic as well as one of high pressure it might also to a certain extent be venous. Where would medical skill come in if an attempt were not at once made to correct matters? What were a nutritious dry diet, calomel hydragogue purgatives, iodide of potassium potassium nitrate, strophanthus, &c intended for? A full nutritious diet will be of most service after suit able measures than the reverse. His uræmic septua genarian I have met and successfully treated by good full generous diet after introducing him therapeuti cally to Broadbent Morison Bradbury and others. His octogenarian with fixed thorax is not hopeless for no doubt some modern surgical Philistine will perhaps some day proceed to resect his ossified costo-sternal cartilages and attempt to make false joints which if he succeeds, will deprive the orthodox physician person of another of his pet cases which he does not now benefit— spare or full diet. I surmise in the event of success a full diet would be more desired than a spare" one. Most decidedly there are cases which a full diet will not benefit, but, on the other hand, a spare diet will get them no further towards recovery

Nevertheless worded as was Dr Campbell s appeal in his article of which I complained he appeared to call upon us to give "spare diet" as a general rule. I contested that and am glad to have been of assistance to Dr Campbell in giving him an opportunity to make himself clear and thus to add lustre to his article

---

[2] THE LANCET June 28th p. 1859

From actual observation of old persons I find that on spare diet their "driving apparatus"—the nervous system—begins to go, but on a good full generous diet signs of cerebral degeneration, softening, inability to swallow, &c , pass away, and with them cardiac irregularity, dyspnœa, &c., mend to a great extent, and with this liver, lung, and kidney disabilities are markedly alleviated I must also thank Dr Campbell for not adopting that well known method of controversy, which is either to imagine your opponent a fool who does not know what he is about, or to twist and to turn and to misconstrue his statements so that he appears to casual readers in the light of a fool , for this much thanks I am made to appear, according to Dr Thomas Dutton and Dr Eric Pritchard, as advocating the following laughably absurd conditions, that a male or female nonagenarian (quoted by Dr Dutton) should with my approval, habitually reel home at 2 A.M. under the load of a 27-course dinner with the usual vinous accompaniments, and so on

I think, Sirs, I can, even at the risk of being charged with arrogance, before finally retiring, enumerate the casualties of this guerilla contest. Dr Pritchard is metaphorically killed, slain whilst taking cover behind a post-prandial anthill which he mistook for something more substantial Dr Dutton has come in as a "tame Bojer" on terms of a "nutritious diet," and finally terms are signed with our "Botha of Diet," Dr Campbell, by my paying the 3 000,000 sterling in admitting that some cases are not good to "cram," yet I prefer from experience a "good full generous diet" in most cases

I am, Sirs, yours faithfully,

July 21st, 1902. F W FORBES ROSS, M D Edin

To the Editors of THE LANCET

SIRS,—In his article, "Observations on Diet," Section IV , appearing on p 1850 of your issue of June 28th, Dr Harry Campbell quotes a writer as follows "Man is carnivorous It is his misfortune, but it is so" , and continues "One would willingly think otherwise, for who can contemplate with equanimity the wholesale slaughter of animals, with all its gruesome accompaniments, in order that we mav feed on their flesh ? But facts have to be recognised." This statement requires considerable modification. Most men who are carnivorous are so from choice or influence of custom, not, as is implied, by the necessities of their organism, many of the most eminent of our scientific authorities (Owen, Ray, and others) who are best qualified to pronounce an opinion on this point have held that structural anatomical evidence proves conclusively that man is a "frugivorous" animal, and my own personal experience and observation of others have demonstrated to me that man can not only "live," but can attain to a high standard of vigorous and healthy life, on a diet which does not necessitate the "wholesale slaughter of animals, with all its gruesome accompaniments," which Dr Campbell (in common with all men of humane feelings) deplores And here, I may say, I cannot understand the mental attitude of one who is *really* desirous of abolishing or lessening the vast amount of suffering so caused and yet refrains from the first and obvious step of at once ceasing to be a participator in its infliction by abandoning flesh as food because of certain minor difficulties which may arise as to the disposal of bull calves and cockerels should he still find it necessary to partake of "animal products" It is indeed a case of "straining at a gnat whilst swallowing a camel" No beneficent reform would ever be inaugurated did men wait for the satisfactory solution of every minor question connected with it before taking the first radical step

My personal experience is as follows Some eight years ago (having just reached my fortieth year), after a perusal of Dr A. Haig's book, "Uric Acid as a Factor in the Causation of Disease," I reduced my consumption of flesh food to a minimum (an average of one pound per week) with the result that the periodic headaches, spells of mental depression and slight attacks of muscular rheumatism, from which I had suffered for some years, gradually ceased to trouble me Nearly three years ago I adopted an absolutely non-carnivorous diet for ethical reasons The results have been more than satisfactory , "uric acid" symptoms no longer trouble me , I have gradually experienced a sense of general wellbeing, health, and energy which recalls my boyhood's days The "sensation of fatigue" after long continued and arduous muscular or mental exertion is very much less than aforetime, and more speedily recovered from, and my resistance to disease is increased as demonstrated by the fact that whereas I used to suffer in winter from a series of "heavy colds in the head," for the past two years I have only had two such attacks which cleared up in three days instead of taking the usual three weeks or so I am acquainted with at least 20 abstainers from flesh foods within a radius of 12 miles (including two medical men, architects, lawyers, &c) whose experience has been substantially the same as my own and whose consciousness of the improvement in their physical wellbeing is such that they unanimously declare that they will never return to their former diet They simply smile at the suggestion that their non carnivorous diet produces "tendency to obesity" or "lowers their energy and resistance to disease," for experience has taught them that, in their cases at least, such theories are without foundation

The fact that the number of meals and quantity of food taken tends to increase among flesh eating communities is a significant commentary on the alleged superior sustaining qualities of flesh Such increase, in fact, is due to quite another cause—i e , the "extractives" of flesh (consisting mainly of the effete products of cell metabolism and belonging to the "uric acid group") are true stimulants, and following the "stimulant" period of their action comes the inevitable reaction with depression demanding fresh supplies of stimulant for its removal Among non flesh eaters the invariable tendency is to simpler fare, fewer dishes and fewer meals

The questions as to the action of excess of uric acid and its allies in the body in the causation of disease and to what extent such excess is due to flesh eating are, I am aware, still under discussion by many members of the profession But that both are productive of disease is the general opinion is shown by the almost universal consensus in the dietetic treatment of gouty and rheumatic affections—i e , the withholding or reduction of flesh foods during their incidence I believe that a very large percentage of diseased conditions is due to this excess and to the habits of gluttony fostered by the stimulating effects of a flesh diet.

The number of those who refuse to recognise the necessity of such a diet, and the resultant infliction on their subhuman fellows of the miseries of forced feeding, long transit by land and sea, and the all too-frequent barbarities of the slaughter house, is happily rapidly increasing, and it is becoming necessary for the medical attendant to be able to speak from a practical standpoint on the diet question , this position he can only attain by experience, for no one should presume to dogmatise respecting it till he has made trial of a non carnivorous diet (intelligently arranged as regards food contents) for at least six months I venture to prophesy that such an experience will result in nothing less than a complete transformation in the present opinions of the vast majority of the experimenters

I am, Sirs, yours faithfully,

ROBT H. PERKS, M.D Brux , F R C S Eng

Paignton July 7th, 1902.

THE MEDICAL SERVICE OF THE MERCANTILE MARINE

To the Editors of THE LANCET

SIRS,—As a quondam ship's surgeon permit me to give my experiences Financially, £10 a month was the maximum, £5 the minimum, this not including fees for severe cases calling for extra time and attention I certainly think that no medical man should go to sea for nothing, as many do If every man insisted on a wage for work it would be given, but this would necessitate the formation of a league, which, seeing that ship's surgeoncies are but temporary, would be difficult of formation Socially the life is delightful, infinite the variety of type and character If you happen on a ship where the skipper, mates, and engineers work well together—a happy family indeed—all's well with you and the passengers Stick to that ship But if you join where the deck and engine room are at feud, woe betide. A stroll with the skipper upsets the chief engineer and a smoke in the chief s cabin lights fires of indignation in the captain None but a diplomat can be happy for long on such a boat The souls of shellbacks are sensitive if their stomachs are tough Educationally, it is beyond price for a man just leaving hospital

On one line I was in sole medical charge of close on a thousand emigrants. I who had never vaccinated had to vaccinate by the hundred never having given an anæsthetic I chloroformed and performed minor operations at the same time not having seen fever rashes I had them to diagnose and it was a nice point, indeed, to differentiate vaccinia, varicella, variola, and varioloid. Then again, a breech presentation with uterine inertia in a gale of wind with a big beam sea, afforded considerable physical as well as mental exertion On ships going East skin eruptions on Chinese coolies are extraordinary and amazing and the vagaries of malaria are still more so to the inexperienced On one ship I sat officially at the head of a table with a bishop and his daughter on my right hand and a couple of American low comedians, fond of cognac in their coffee, on my left. This too was instructive. Another point of view educationally is of importance—viz. the art of playing poker At first your month s pay and more—much more—vanish but at the year s end, *experientia docet* as it does in most things.

A life at sea for a year or two is good for a man. On some ships there is little or no work on others a great deal too much, but he leads the life of a gentleman if he is one, lives well sees the world, is not bound by service rigidities, and his horizon is considerably broadened. The 'great green mother brings forth memories pleasant in after life. Abject is an asinine adjective (what the user thereof is must be left to logic) to apply to steamship doctors," unless of course, they suffer from sea sickness when it is æsthetically appropriate *Cœlum non animum, mutant qui trans mare currunt*

HORSE DUNG IN LONDON STREETS

To the Editors of THE LANCET

SIRS,—That the horse is a nuisance in the streets is beyond doubt, but how great a nuisance has not yet been shown. On several occasions I have noticed that the deposit of manure from London stables on fields in the open country has been followed by outbreaks of diphtheria in the scattered cottages near by Town medical men attribute summer sore-throats to the dryness of the wood pavements which are constantly fouled with horse droppings, and I would suggest to those occupied in bacterial research the advisability of an inquiry into the possibility of the propagation of diphtheria through infected discharges from an animal immune to the disease by inoculation

I am Sirs yours faithfully
H BEALE COLLINS.
Health Department Kingston-upon Thames, July 19th 1902.

To the Editors of THE LANCET

SIRS,—Your suggestion that some form of light scavenger, motor propelled" might be employed to remove speedily horse-dung from London streets, seems to me much more practically useful than that of Dr F E. Fremantle who advocates the total suppression of horses and the general introduction of motor cars The horse" says the latter is no longer a necessity to its owner he is a luxury and to the public he is a nuisance. It is obvious to any schoolboy that four fifths of London horses are not luxuries to their owners and as compared with the nuisance of motor cars, as at present constructed and run, horses are positive comforts. Where motor cars as in Paris and the Riviera, are much driven the public regard them as pests, which scare them smother them with dust and tax all their resources of nerve and muscle to avoid. They are withal very ugly (especially their occupants) noisy and unhealthy Till motor cars supplant horses something more radical and resourceful than the present system of merely watering the gutters wants doing in London streets. Might not the pathways sometimes be swept and cleansed in dry weather and might not successors be found for the smart little street boys whose disappearance with their dust-pans is so much missed? On returning to London from abroad one is always struck by the excellent paving of the London road and the way in which their hygienic merits are neutralised by the straw laden atmosphere due to the constant circulation of desiccated and neglected horse droppings Now that you have called attention to this defect it is to be hoped that something may shortly be done to remedy it.

I am Sirs yours faithfully
Ashley-gardens, S W July 21st 1902. D W SAMWAYS.

THE TREATMENT OF INTRA-PERITONEAL ABSCESS OF THE APPENDIX

To the Editors of THE LANCET

SIRS,—One important point raised by Mr F C Wallis s paper on the above subject in THE LANCET of July 19th, p. 145 touches the use of natural sponges in abdominal surgery Mr Wallis says marine sponges should not be used, and recommends Gamgee tissue both for the purpose of protecting the sound peritoneum and for cleansing the abscess cavity It is only the importance of small matters in practical surgery that makes me desire to record my conviction that for abdominal work well-chosen marine sponges *when properly prepared* are better from every point of view than any artificial sponge. They leave no fibres or fragments behind—a drawback that every substitute made of gauze and cotton wool is bound to have. Such fibres or fragments are foci for re infection in cases where pus is present. Marine sponges when moist with sterile salt solution absorb liquids more readily than absorbent wool and they are less harsh and less likely to injure the delicate endothelial covering of the peritoneum than are any swabs covered with gauze. The only real drawback to the use of marine sponges that I know is the trouble which they give in preparation—a process which the surgeon should be personally responsible for

I am Sirs yours faithfully,
Portland place W July 19th 1902. J JACKSON CLARKE.

DIPHTHERIA AND ITS TREATMENT AT COLCHESTER

To the Editors of THE LANCET

SIRS —It seems barely possible to imagine that the letter of Dr George Brown in THE LANCET of July 19th 1902, p. 182, is intended to be taken seriously and yet if it be intended as a satire on those who still refuse to believe that bacteriological examination and antitoxin are of any use in diphtheria the satire is too delicate for my perception. There is scarcely a statement in it which even borders on correctness. Remove the cause and the effect ceases. Yes, remove the diphtheria bacilli from the throat and of course there will be no subsequent paralysis provided they are removed *before they have got there* In no instance is it probably less correct to apply this maxim. It would be as reasonable to say remove the cannon ball and the house it has knocked down will re-erect itself "

Dr Brown s account of the morphology of the epithelium of the naso-pharynx is ridiculously at variance with facts and his knowledge of the functions and distribution of ciliated epithelium and of its physiology in general must be derived from an unpublished work of his own for certainly it is shared by no one else

I have always thought that the finding of a specific for a disease, a remedy which could be relied on to cure was the highest development of either medicine or surgery Dr Brown evidently prefers to have several strings to his bow It might have been thought that the discovery of a remedy which would cure every one of 375 cases of diphtheria treated with it on the first day had some claims to be considered an advance in medicine. Dr Brown has come to judgment and we who believe in and advocate the use of antitoxin and are foolish enough to think that there is good in it must hide our diminished heads.

If I transgress the courtesies of debate I am sorry but every letter like that of Dr Brown means the encouragement of others of the same way of thinking of whom the number is still lamentably large. The statements about tetanus, severe urticaria, and other serious maladies" are the kind of thing which one might expect to meet with in the columns of the *Anti vaccinator* but scarcely from a medical man of good standing discussing a scientific subject in a fitting spirit. Will Dr Brown be good enough to mention a few say half a dozen of the other serious maladies?" That tetanus has followed when tetanus bacilli were contained in the serum is unfortunately true, but it is no more fair to charge antitoxin with the result than it would be to attribute to sugar the death of a person who had accidentally taken sugar which was mixed with oxalic acid Jenner's great law "that the protective principle must be introduced into the system before the disease it is used for breaks out" is no law at all and it would be interesting to know whence Dr Brown obtained it Possibly from another of his own unpublished works In any case, the attempt to draw a parallel between scabies and diphtheria does not tend to inspire confidence in the deductions in general of the writer

I am, Sirs, yours faithfully

Old Kent-road, S E, July 23rd 1902 EDWARD C BOUSFIELD

To the Editors of THE LANCET

SIRS,—Dr G Brown's letter in THE LANCET of July 19th expresses the reliance to be placed on bacteriological diagnosis and treatment by antitoxin as premature, and for my part I believe he is right and I think that this view is shared by many practitioners in the borough What can be said of the following experience? Three of a family one after the other were attacked with sore-throat and exhibiting all the signs of diphtheria. The medical officer of health was notified who subsequently took swabs from two of the family Afterwards he declared the results were negative Within the past four months I took swabs from four cases, all showing clinical signs of diphtheria, and in each case the medical officer of health of Colchester, who took charge of the swabs, returned the report marked "No result"

With regard to treatment by antitoxin, I have examined three cases of children who were subjected to the remedy a few months previously At the time of examination I found two suffering from albuminuria and one from albuminuria and bronchitis, from which latter it died. It may be said that these diseases will exist no matter what is done Well, that is so, but it is peculiar that a remedy such as antitoxin, praised as infallible, should leave a grave sequel such as the above In the town of Colchester two medical men almost went mad over the treatment on public platforms and by long letters in the lay press condemned all but antitoxin, which latter was, in their opinion, specific It is grave to think that men of long experience in epidemic disease and who love their profession should not be permitted to have an opinion other than that manufactured for them Antitoxin may be good, but is it possible that other treatment might also be good?

I am, Sirs, yours faithfully,

Colchester July 23rd 1902. H. WHITBY

⁂ Dr Brown's attitude towards the antitoxin treatment of diphtheria having been commented upon in our columns we considered it right to allow him to state his views A similar desire to hear both sides induces us to publish Mr Whitby's letter We have already declared, in connexion with Dr Brown's position, that it is impossible for us or anyone to lay down that a certain therapeutical proceeding is the one and only proper course to be pursued in any disease But Dr Brown called the use of antitoxin in diphtheria "bowing the knee to medicinal Baal,' which was an unfortunate attitude for a medical officer of health to assume towards the treatment which happens to be accepted by practically the whole medical world as valuable —ED L.

PATENT FOODS

To the Editors of THE LANCET

SIRS,—In the lecture delivered by Dr Robert Hutchison, and reported in your issue of July 5th p 1, I note that with regard to Mellin's food, the lecturer is reported to have said "Mellin's may be used, but it is extremely poor in fat" A moment's reflection and doubtless Dr Hutchison would have added "Which is supplied by the milk or cream with which the food is directed to be made'

I am Sirs, yours faithfully,

WALTER SCOTT, M R C S Eng, L R C P Edin, &c.

Tulse-hill S W July 16th 1902.

CIDER AND GOUT

To the Editors of THE LANCET

SIRS —There is a letter on the above by Dr T Dobson in THE LANCET of July 19th, p 182, in connexion with which I may say that many years ago, whilst living in Somersetshire, one of our cider counties, I made some investigations on this subject, the results of which were published by Dr (now Sir) Alfred Baring Garrod in the second edition of his "Gout and Rheumatic Gout," p 592 (Walton and Maberly, London, 1863), and which may be summed up as follows *Sound* cider—i.e., cider of low specific gravity—completely fermented and containing neither acid nor sugar, is equivalent to a sound and *dry* wine and may be taken by the gouty with benefit, whereas, on the contrary, *sweet* cider, like imperfectly fermented beers, ales, and wines, is hostile to those disposed to gout on the principle that when *sugar* and *alcohol* meet in the stomach they become mischievous

This subject I referred to again more fully in an unsigned article I wrote for Dr Robert Druitt which he published in the *Medical Times and Gazette* of April 27th, 1867, under the heading "Cider for India."

I am, Sirs yours faithfully,

July 22nd 1902 ALFRED HAVILAND

MALARIA (?) IN THE LOWER ANIMALS

To the Editors of THE LANCET

SIRS,—When in London I always endeavour to spend an hour or so in that delightful and creditable national institution—the Natural History Museum Last week I had the privilege of visiting it and of seeing for the first time that most beautiful case containing the biology of the mosquito, the modelling of which is so inimitably done by a lady On the descriptive letterpress attached I read, "Malaria is a disease peculiar to man," and my object in writing to you is to ask, is this an established fact? Because, when up in an arid, shaly, treeless district of Afghanistan we had over 100 cases of virulent malaria which I recommended to be moved down to shade and grass for milch cows Our excellent commissariat officer, who, like General French, not only "never made difficulties," but would never *see* any, and who got me the cows from Heaven knows where, asked me to see his favourite down country pony which had regular rigors followed by profuse sweating I concluded, rightly or wrongly, that it had this severe malaria, and I proceeded to give large quantities of quinine in rum and frequent gruel, and although it resisted these at first, it soon whinnied when it heard my step and, unable to stand, held up its head, and sucked down its "bottle" and completely recovered Now was not this really malaria? It had all the symptoms of it and quinine undoubtedly cured it I may add that in that "sick camp" I had many interesting experiences as to the value of local herbs in endemic diseases

I am, Sirs, yours faithfully,

July 21st, 1902. W M. H.

NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT)

The Plague Epidemic —The Monsoon.—Cholera and Plague Inoculations

THE plague epidemic has sunk to almost insignificant interest During the last fortnight the mortality has declined with rapidity, but we have apparently reached, if not passed, low water mark, because there has been a slight rise again almost everywhere For the week ending June 28th 1684 deaths were returned as due to plague, as compared with 1294 for the previous week and with 821 for the corresponding week last year The Bombay Presidency had 554 deaths, as against 279, the Punjab 1026, as against 721, Karachi 12, as against 19, Madras Presidency 32, as against 22, Bengal 57, as against 27, the United Provinces 33, as against 39, and Mysore 170, as against 139 This slight and general rise is coincident with the commencement of the rainy season but is not necessarily to be attributed to it. I may remark once more that plague outbreaks seem quite independent of season (rain, sunshine, cold, or heat), of altitude, or of climatic conditions generally

The monsoon, which it was at first thought would be at least an average one, has largely failed and the prospects are now most unfavourable, especially for Western India.

Inoculation for cholera, like that for plague, has lamentably fallen off, not from any decline in its value, but apparently from the indifference of authorities and because it is left optional to the labourers as to whether they will avail themselves of it. In the few instances in which it was practised last year the results were satisfactory The same with plague. While by personal influence in Gaya over 20 000 inoculations were performed the number done in Calcutta could almost be counted on the fingers The results in Gaya proved very satisfactory The mortality from plague is found to vary in the rural and urban areas. In Bengal during 1901 there were 90 762 cases recorded with 78,629 deaths which compared with the previous year shows a decline of case mortality from 95 7 to 86 6 but at the same time in Calcutta the rate of mortality was 91 5 against 86 1 in the interior There is no satisfactory explanation of this given In the Sanitary Commissioner's report the editor rightly argues in favour of inoculation as against disinfection, but the Lieutenant-Governor is unable to accept his arguments. There is very little evidence to show that disinfection as practised is of any value, while the results of inoculation are unmistakeable The principle of vaccination against small pox is to render the people immune to this disease and so it is with inoculations for plague, but the authorities can hardly be said to encourage it.

July 4th

FEES TO MEDICAL WITNESSES

(FROM A LEGAL CORRESPONDENT)

So much has been said and written with regard to the payment of medical practitioners for their services as witnesses that a concise statement of the existing law upon the subject may be found useful. Increase in population and the increased popularity of the medical profession have made serious inroads upon the time at the disposal of the practitioner but even this has not had the effect of inducing those who have the power to bring about the payment of a living wage' to the medical man who is compelled to spend his valuable time at a court of justice A bare statement of the law with regard to the duty of a witness who is subpœnaed to attend the hearing of a case at any court ought to be sufficient to show that adequate compensation should be given to any professional man who is called upon to fulfil such a duty Lawyers of course like other people, suffer from the law's delays but they take good care to obtain additional fees for the waste of time which is occasioned by attendance at court. Moreover when we bear in mind the importance of the issues which sometimes depend upon the opinion of a medical witness it is surprising that remuneration should be based upon the present parsimonious basis.

The following is a list of the places in which the services of medical men are sometimes required (1) Parliamentary Committees (2) the High Court of Justice (in all its various departments) (3) assizes, (4) courts of quarter sessions (5) police courts and (6) coroners inquests The following figures, which are for the most part taken from Glenn's ' Manual of the Law affecting Medical Men (1871)) give the *existing* scale of expenses which are allowed to medical men on taxation. In the House of Lords the taxing master is bound by the following scale —

—	Time.	Per diem (hotel expenses if from home)
	£ s d.	£ s d.
Apothecaries chemists and druggists	1 1 0	1 1 0
Physicians and surgeons ..	2 2 0	1 1 0

Higher charges are under special circumstances sometimes allowed Sundays do not count as time. For travelling expenses the sum necessarily expended is allowed Although the attendance of medical men is but rarely required at the House of Lords except in cases where money is no object, the scale of fees above set out is very much too low especially in view of the high fees usually allowed to persons having business in the Upper House. The proviso that Sundays do not count as time" is ungenerous in the extreme for a country practitioner might well make a claim in respect of his absence from his practice on Sunday

The following are the fees allowed on taxation in the various branches of the High Court of Justice —

In the King's Bench Division and Chancery Division

Per diem if resident in the town where the case is tried (i.e in one circuit town or assizes or London when the case is tried at the Royal Courts)	£1 1 0
Per diem, if resident at a distance from the place of trial inclusive of all except travelling expenses. [If the witness attends more than one cause, he is entitled to only a proportionate part in each case] ...	£2 2 0 to £3 0

In the Probate Court

Per diem, if resident within five miles of the General Post Office	£1 1 0
Per diem if resident beyond that distance (including board and lodging)	£3 3 0

In the Divorce Court.

Per diem if resident within five miles of the General Post Office	£1 1 0
Per diem if resident beyond that distance (including board and lodging)	£2 2 0 to £3 3 0

In the Admiralty Court.

Per diem whether required to come a distance not exceeding two miles or not (including board and lodging)	£1 1 0 to £3 3 0

In each of the above cases the amount reasonably and actually expended for travelling expenses is allowed provided that it does not exceed the sum of 1s per mile one way In the bankruptcy court, which forms part of the high court of justice, the following scale is used —

Per diem if resident in the town in which the court is held	£1 1 0
Per diem if resident at a distance from the court, including subsistence	£1 1 0 to £3 3 0

In this case travelling expenses are allowed at the rate of 7*d* per mile one way where there is no railway available, or travelling expenses actually incurred in the discretion of the taxing officer

The above figures were true in 1870 and, subject to certain unimportant modifications consequent upon the fusion of some of the divisions of the High Court to which they relate they are in force at the present time. In any case there has been no substantial alteration. They appear to have been drawn up for the convenience of professional men who can make a protracted visit to London by the simple expedient of altering a list of engagements, they are certainly not intended to compensate a medical practitioner who must be at the beck and call of his patients at all hours of the day and night

In the county courts, where medical men are sometimes subpœnaed to render assistance to one or other of the parties the following scale is used —

Medical men as ordinary witnesses (per diem)..	£0 15 0 to £1 1 0

Medical men as expert and scientific witnesses	If costs taxed on ordinary scale	If costs taxed on the higher scale
	£ s d £ s d	£ s d £ s d
For qualifying to give evidence ..	1 1 0 to 3 3 0	1 1 0 to 5 5 0
Attending court on trial (per diem)	1 1 0 to 2 2 0	1 1 0 to 3 3 0

All the above figures are intended to be used as a guide to the amounts which may be allowed by taxing masters when settling the bill of costs to be paid by the unsuccessful party to a suit. There is nothing to prevent a medical practitioner entering into an agreement under which he may claim greater remuneration, but it has been decided that if a medical witness is compelled to bring a suit to recover for his services as a witness he can only recover the amount allowed by the rules. Further the above figures may be used as a scale upon which an estimate may be drawn up if all payment is refused.

With regard to every claim for services rendered as a witness in a civil case it is sometimes said that a witness is entitled to refuse to give evidence unless his expenses are paid and, further that he is at liberty to claim conduct money when a subpœna is served upon him But conduct money" often amounts to a mere nominal payment and a witness who refuses to be sworn until his fee is paid has but poor consolation for his trouble in going to the court. In a recent case in the Leeds County Court before His Honour Judge Greenhow which has given rise to much comment, the medical officer of a public charity in Leeds refused to be sworn to give evidence for the plaintiff unless his fee of £1 1s was paid. In the result he was not compelled to give evidence, but he was, nevertheless, put to the trouble of attending the court and his conduct was made the subject of severe and, it is submitted, wholly unwarranted criticism on the part of the learned judge.

The consequences of disregarding a subpœna to attend to give evidence are severe both in the High Courtand in the county courts A witness who disobeys a subpœna issued out of the High Court after having had his expenses paid or tendered may be committed for contempt, although he cannot be proceeded against for making default unless it appears that a reasonable and sufficient sum of money to defray the expense of coming and going was tendered to him He is also liable under an old statute passed in the reign of Queen Elizabeth to an action at the hands of the party who suffers damage by reason of the evidence not having been forthcoming To the rule that conduct money must have been tendered before the court can make an order upon a motion to commit a witness for contempt, there used to be an exception in a case where the witness lived in the town where the court is held, but it is not certain that this exception would hold good at the present day

It is provided by the County Courts Act (Section III.) that any person summoned to attend as a witness, to whom at the same time payment or a tender of payment of his expenses shall have been made on the prescribed scale of allowances, who refuses or neglects to appear, or who shall refuse to be sworn or to give evidence, shall forfeit and pay such fine, not exceeding £10, as the judge shall direct

The foregoing statement of the law will have made it plain that the existing scale of fees is capable of rigid enforcement, and the treatment which one practitioner received at the hands of the county court judge is not likely to tempt others to stand on their strict legal rights.

Turning to the courts of criminal and *quasi*-criminal jurisdiction we find the position of the medical practitioner very little better Except in certain special cases an offer of expenses is not necessary in order to secure the attendance of a witness in a criminal trial. This is upon the ground that attendance at such a tribunal is a public duty It is, however, provided by the 45 Geo III, cap 92, section III., that where a witness is called upon to give evidence in another part of the kingdom and is served with a subpœna for the purpose a sufficient sum to defray his expenses must be tendered at the time. In pursuance of this principle the Home Secretary (by virtue of the 14 and 15 Vict, cap 55) has ordered that medical men shall be remunerated in criminal cases in assizes, &c., upon the following scale "To prosecutors and witnesses being members of the profession of medicine attending to give professional evidence for their trouble, expenses, and loss of time, for each day they shall necessarily attend the court to give professional evidence a sum not to exceed £1 1s For each night, if detained all night, 2s, and if they shall attend from a distance, for mileage, per mile each way, 3d"

Under the Indictable Offences Act, 1848, power is given to justices to require any person to appear to give evidence, if it shall appear to the justices that the evidence of the witness is material. If he refuses to appear without a just excuse, then, after proof of the service of the summons, the justice may issue a warrant in order to bring him before the court. It seems that in such a case a tender of expenses is not absolutely necessary but in 1893 Lord Brampton (then Sir Henry Hawkins) expressed the opinion that solicitors have no right to bring a person a long way without providing travelling expenses, and it is enacted by the Summary Jurisdiction Act, 1848, that *upon proof*, but only upon proof, of expenses having been tendered the justices may order a defaulting witness to be brought up on a warrant.

If a medical witness is practically at the mercy of the litigants in a civil case he is at the mercy of the Crown when summoned to a criminal court. It may be said that it is part of the duty imposed by statute upon a medical man that he shall give his services to promote the ends of justice, but it is difficult to understand why services so rendered should not be adequately compensated. All who have attended assizes and quarter sessions know how medical men are kept in attendance for days until cases in which hey have been bound over to appear come on for hearing

Even in the coroner's court, where the presence of one or nore medical witnesses is practically essential, the scale of es allowed is absurdly low It is provided by the Coroners ct, 1887, that a medical practitioner may claim "(*a*) for attending to give ev [illegible] any inque mortem-examination has been made by one guinea, and (*b*) for making a post-m of the body of the deceased, wi analysis of the contents of [illegible] for attending to give evidenc [illegible] rule is subject to the proviso [illegible] the body of a person who had [illegible] hospital or "other medical [illegible] (in officer whose duty it may have [illegible] to atten is not to be entitled to any fee. The scope may be gathered from the case of Horner *v* 524), in which it was decided in 1898 that a c comes within the meaning of the phrase " institution" as used in the section, with the honorary surgeon of such a hospital can obtain the coroner

It is apprehended that after reading the for ment of the existing law with regard to the rem medical witnesses an impartial critic would b the conclusion that members of the medical pro grossly underpaid for the important services whi compelled to render to the public.

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Liverpool Convalescent Institution.

AT the annual meeting of the Liverpool Conv Institution at Woolton, the secretary drew the atten the subscribers to the satisfactory progress made in the of the institution as evidenced by the increase in the n of patients during the last year, the total amount 2672—the highest number attained The financial po of the institution might be considered to be satisfac The gross receipts from all sources showed the slight fa off of £68, but this was more than counterbalanced by decrease in payments for special purposes, maintena and extension, which were heavy during the previous th years. There was a credit-balance at the bank of £1 The subscription list again showed an augmented tot a very healthy feature, and indicative of increasing pop larity and appreciation. The annual subscription list ha increased from £679 in 1891 to £1001 in 1901. Mr J W Hughes had enabled the committee to raise the number o free beds to 14 by a generous donation of £21 a year The subscribers made a liberal use of the nomination and recommendation forms which were supplied to them, the former admitting patients free of charge and the latter at the reduced rate of 5s per week. The amount received from patients for extension of time—£1667—testified strongly to their appreciation of the benefits resulting from the change of air and scene. The Lord Mayor of Liverpool alluded to the advantages and usefulness of such an institution where patients who were convalescent might go to be restored to health and strength

Proposed County Sanatorium for Cheshire

Deputations from the various town councils, boards of guardians, district councils, and sanitary authorities over the whole of Cheshire met the health committee of the Cheshire County Council at the North Western hotel at Crewe last week to discuss the necessity of providing a sanatorium or sanatoriums for the treatment of patients suffering from tuberculosis resident in the county Mr D B Hewitt of Northwich, who presided, dealt with the proposal at length and said that the total number of deaths caused by that disease in Cheshire during the four years amounted in 1897 to 638, in 1898 to 683, in 1899 to 646, and in 1900 to 598. It was proposed and seconded

> That a sanatorium or sanatoria should be established in the county for the treatment of consumption

Mr W Hodgson, L R C P Irel., county councillor, said that this question had been before the county for a considerable time, and it was absolutely necessary that something should be done But if they did not adopt compulsory notification they could not have a sanatorium. The motion, amended so as not to commit the authorities absolutely to the votes of representatives, was then carried.

The Special Appeal on behalf of the Stanley Hospital.

The serious condition of the finances of the Stanley pital was alluded to in THE LANCET of the appeal by the committee to the citizens of Liverpool for funds to enable them to keep the hospital open has resulted in promises of subscriptions of £1805 to date The charity is in debt to the amount of £5000

Hospital for Women, Shaw-street

The honorary treasurer of the Hospital for Women gratefully acknowledges a donation of £500 from Sir William Tate, Bart. to the general funds of the hospital. This generous gift has proved most opportune and will enable the committee to have both the interior and the exterior of the buildings painted and put into thorough repair a much needed improvement which could not be done earlier owing to lack of funds.

The Liverpool Royal Infirmary

Dr Richard Caton the senior physician to the Royal Infirmary will shortly retire through lapse of time. Dr Caton was appointed honorary physician in 1886 having previously been honorary physician to the Northern Hospital.

West Derby Board of Guardians and Sane Epileptics

At the last meeting of the West Derby board of guardians Mr I. Holmes, L.R.C.P. & S. Edin. (vice-chairman of the board) reported that he had attended on behalf of the board, the conference at Manchester of the representatives of the Lancashire unions convened for the purpose of considering the best means of providing accommodation for sane epileptics. The Manchester and Chorlton unions did not take any part in the conference. It was decided to form a colony and to erect buildings, but the difficulty arose as to ways and means and how they were to carry out such a scheme. A small sub-committee was appointed to inquire into these matters and to see what each union in the county was prepared to do. He had come to the conclusion that it was time that the West Derby Union withdrew from the scheme, which would practically mean with the cost of land and buildings, an expenditure of £80 000 and each union belonging to the combination would be expected to pay *pro rata*. It was stated that outside Manchester and Chorlton there were about 350 sane epileptics in Lancashire. It was proposed that the Government should buy the land and erect the buildings, but a Local Government Board inspector expressed the opinion that such an undertaking would not take place in the life-time of the present generation. In the West Derby Union they had accommodation at Elm House for at least 80 epileptics, and although many were insane they were not all unmanageable and they did not interfere with the sane patients. This accommodation, which was practically sufficient for a quarter of the sane epileptics in Lancashire, would meet their requirements for many years to come, and he would urge them not to take part in the scheme although he was quite in sympathy with its objects. The board agreed with Mr Holmes's views and resolved to withdraw from any further action in the matter

Cancer in Cheshire

Mr Francis Vacher the medical officer of health of Cheshire, in his recently published annual report draws attention to the large number of deaths occurring annually in Cheshire as the result of cancer In 1901 there were 538 deaths caused by this disease, as against 439 in the previous year Any contribution to the better understanding of so terrible a disease, he says, should be welcomed, and most medical officers of health could contribute some facts and observations. There are many points as regards cancer which require elucidation — Is cancer a parasitic disease? Is it infective? Does it haunt houses and places? Is it communicated by domestic animals? Is it associated with the ingestion of any food, animal or vegetable? Is the disease increasing?

July 22nd.

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

The Prevention of Tuberculosis.

WHEN the South Wales and Monmouthshire branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis was formed in October 1901, the executive committee was empowered to promote the establishment upon a partially self supporting basis of open air sanatoriums for patients suffering from tuberculosis and at a meeting of the committee held at Cardiff on July 11th a report dealing with the subject was adopted It is suggested by the committee that in the first instance a sanatorium to accommodate 20 patients shall be erected for Glamorganshire and Monmouthshire. The initial cost is estimated at £5000 and the cost of maintenance at £80 per patient, or £1600 annually It is proposed that the £5000 shall be obtained by voluntary contributions but that the annual sum of £1600 shall be provided by the two county councils the county boroughs of Cardiff, Swansea, and Newport, and the 53 urban and rural sanitary authorities in the two counties. The committee instanced the action of the Westmorland county council which contributes £110 yearly towards the maintenance of the county sanatorium where there is accommodation for 22 patients although the population of the county is only 64 000 and the rateable value only £436 000. The chairman of the Monmouthshire county council moved the adoption of the committee's report, which was not, however allowed to pass unchallenged. Dr J O Bowie of Cardiff contended that the sanitary authorities could spend the ratepayers money to better purposes by improving the conditions under which so many persons were compelled to live and he expressed some doubt as to the ultimate good which accrued from treatment in a sanatorium In connexion with the notification of phthisis it is of interest to quote the experience of the medical officer of health to the Llandaff and Dinas Powis rural district (Dr R. Prichard). In August, 1901, the district council on the recommendation of Dr Prichard, invited the medical practitioners in the district to notify cases of consumption occurring in their practices and offered a fee of half a-crown for each certificate. Up to the end of the year only one certificate was received and that was after the death of the patient During the whole year there were 25 deaths from phthisis so that the absence of certificates cannot have been due to the absence of cases to certify

Carmarthen Asylum.

The joint counties asylum at Carmarthen serves a population of 283,000 persons living in Carmarthenshire, Cardiganshire and Pembrokeshire. It was established in 1865 and has accommodation for 576 patients The medical superintendent (Dr Edwin Goodall) in his annual report comments upon the prevalence of tuberculous disease in the asylum 40 per cent. of the total deaths being attributed to this cause notwithstanding the fact that the open-air treatment has been followed in suitable cases and with encouraging results. Dr W H. Symons of Bath has *shown*[1] that Cardiganshire has the highest death rate from tuberculous diseases of any county in England and Wales, averaging in the decennium 1891–1900 2 4 per 1000 compared with 1 4 for the whole of England and 1 7 for Wales. Dr Goodall advises the erection of a separate block for private patients, and there ought not to be any difficulty in giving effect to this proposal for during the past seven years there has been credited to the building fund of the asylum a sum of £7367 which represents the profit made upon private patients and upon patients received from other counties The average weekly cost per patient is under 10s

Pontypool Hospital

Pontypool is a town with a population of about 6000 persons and is the centre of a large and increasing colliery district. Although it is only about 10 miles from Newport the want of a properly equipped hospital has long been felt and definite steps have now been taken to erect a building with accommodation for 19 patients at a cost of £6300 Two of the beds will be set apart for persons suffering from hernia in fulfilment of an agreement made with the trustees of the late Mr Richard Coslett who died in the year 1895 and in addition to other charitable bequest left £1000 and an annuity of £100 for the establishment and endowment of a hospital at Pontypool for the treatment of poor persons suffering from hernia. As it was found impracticable to carry out fully the intentions of Mr Coslett in this direction Mr Justice Joyce on July 18th gave permission for the sums named to be applied to the erection and support of the general hospital about to be established The colliers in the district have been for many months past subscribing a penny a week each towards the hospital fund and the employers are adding 25 per cent. to the workmen's contributions.

---

[1] Public Health, vol xiv., p. 357

Small-pox.

During the week ending July 19th eight fresh cases of small-pox were notified in Swansea and eight deaths occurred in the small pox-hospital during the same period No cases were reported during the last three days of the week. Of the 140 patients who have been attacked since the beginning of the outbreak not one had been recently revaccinated The Swansea board of guardians is taking very comprehensive steps to ensure the revaccination of as many of the inhabitants of the town as possible and every assistance is being rendered by the local medical practitioners On July 15th a deputation from the Swansea Medical Society conferred with the board, when it was arranged that the town should be divided into 20 districts and that a house to-house visitation should be made for the purpose of offering and performing revacinnation. A fee of 2*s* 6*d* will be paid for each successful revaccination, the lymph being provided by the board of guardians, and the person vaccinated will be expected to present himself for subsequent examination at the surgery of the medical practitioner vaccinating Where the operation takes place at a surgery the same fee will be paid but the board will not supply the lymph Some members of the board of guardians appeared to think that a smaller fee might be accepted, but the president of the medical society (Mr W F Brook) pointed out that house-to-house vaccination entailed a great deal of hard work, for it meant picking up the laggards, many of whom would require a considerable amount of persuasion before they would submit to the operation and frequently more than one visit would be necessary The police have distributed 20,000 cards drawing the attention of householders to the necessity of revaccination and explaining the facilities offered. The sanitary committee of the corporation acquiesced in a suggestion of the medical officer of health (Mr Ebenezer Davies) that the circulation of all books from the free library should be absolutely stopped from all houses unless there was a declaration from the head of the house to the effect that all members of the family over 10 years of age were re vaccinated The corporation, however, would not consent to this proposal being carried out. On July 17th Dr Wilfred W E Fletcher visited Swansea on behalf of the Local Government Board.

Swansea General and Eye Hospital

The annual report of the Swansea Hospital, unlike that of many similar institutions, contains a balance sheet showing an expenditure which has been more than met by income. The total amount of the latter was £6151, and more than one third of this sum was received from periodical collections among workpeople. The expenditure for the year was £5457, the weekly cost per patient averaging £1 2*s* 2*d* The hospital contains 130 beds and during the year ending May 31st 1175 in patients were treated, or 23 more than in the previous 12 months Owing to the prevalence of small pox in the town patients were not admitted from infected districts, the number of out-patients was therefore only 5457, or 654 less than in the year 1900–01

Cardiff Health Report

Dr Edward Walford has just issued his annual report for the year 1901 and like his reports of previous years, it is full of interesting matter The birth rate for the year was 31 4 per 1000, the average rate for the previous 10 years was 35 7 The death rate was 16 per 1000 compared with an average rate for the previous 10 years of 18 5 per 1000, and the rate of infantile mortality was equal to 148 per 1000 births, or 13 below the average rate of the preceding decade. The death rates in different parts of the borough varied from 11 per 1000 in Riverside ward to 17 3 in the central ward When commenting upon the prevalence of scarlet fever in the town Dr Walford expresses the opinion that although hospital isolation may never entirely remove scarlet fever from amongst us it will, if systematically enforced, have the effect of lessening the extent of an epidemic and of extending the interval between epidemic periods, thus reducing the sickness rate and the fatality of the disease by postponing the infection until a later age. Some important investigations have een made during the past two years with a view to ascer ain to what extent overcrowding of dwellings existed in e borough. There were examined 5547 houses and in less an 1 per cent. was there an average of more than two cupants per room. There is evidently, therefore, very le overcrowding in Cardiff

uly 21st.

IRELAND

(FROM OUR OWN CORRESPON

Public Health of Dublin

THE Council of the Dublin Sanitary A July 17th at the offices of the association, and had under consideration the spread epidemic of measles in the city and su following motion was passed unanimously —

> That the council of the Dublin Sanitary Associat cern the following facts relative to the spread of th in Dublin at present. According to the weekly repor General for the week ended July 12th no fewer thar disease were notified in the city and 24 cases in Pemt are available for Rathmines The admissions to ho patients were only 45 during the week and at the close 163 cases in all were under hospital treatment The opinion that a special staff of district nurses shou during the stress of the epidemic to visit the children whom the necessary hospital care is not available.

The managing committee of Cork-street Fever on July 10th when the registrar reported tha recently been a great demand on the hospital be the epidemic of measles, happily of a mild type. not been any new case of small pox in Dublin an tution at Finglas in which patients suffering disease were lodged is soon to be reopened for th of convalescent cases of scarlet fever

Royal Hospital for Incurables, Donnybrook, Du

Owing to the generosity of Mr William Fry, the of the above institution, an entertainment was give poor patients there on July 17th. During its prog following telegram was forwarded to His Maje King —

> His Majesty the King Royal Yacht Cowes
> 206 patients in the Royal Hospital for Incurables assemble entertainment given by the chairman in honour of the Cor tender their most respectful and loyal congratulations to His M the King and desire to express their heartfelt thanks to Almigh for His Majesty's continued progress towards recovery from his serious illness
> WILLIAM FRY, Chairm
> Royal Hospital for Incurables, Dublin, 17th July, 1902.

The following reply was received —

> William Fry, Royal Hospital for Incurables, Dublin
> Am commanded to express His Majesty's thanks to the patien the Royal Hospital for Incurables for their kind telegram.
> KNOLLY

Richmond District Lunatic Asylum, Dublin.

The monthly meeting of the committee of management the Richmond District Asylum was held on July 18th the Board room, North Brunswick-street, when the resigna tion of Dr D F Rambaut was received. Dr Rambau filled the office of resident medical officer and pathologist to the institution for some years and is now about to leave Dublin Mr Conolly Norman, the resident medical superin tendent, spoke in very complimentary terms of the services of Dr Rambaut, and the following motion, proposed by the chairman, was passed unanimously —

> That we desire to place on record our complete satisfaction with the manner in which Dr Rambaut has discharged his duties whilst in the service of the institution, and, though we regret he is now leaving Dublin we congratulate him upon his recent appointment to the charge of Shrewsbury Asylum

The Small-pox Outbreak in Belfast

At a meeting of the Belfast board of guardians held on July 15th it was reported that no new cases of small pox had occurred since the last admission which took place three weeks before, so it may be said that the epidemic has been overcome. The number of cases—all convalescent—remaining in the union hospital is 12. Too much praise cannot be given to Dr A G Robb, who had charge of the cases, and all the officials at the union workhouse for the great success which the efforts made by them have attained in the stamping out of this epidemic, especially as the patients were placed in a building adjacent to which there are over 5000 inhabitants in the workhouse.

North of Ireland Branch of the British Medical Association.

The annual meeting of the North of Ireland branch of the British Medical Association was held in the Belfast Museum on July 17th, the President, Dr J S Darling (Lurgan), being in the chair The minutes having been read and passed the annual report and financial statement were passed. From these it would members elected the membership of the North of Ireland branch is now 307 making the branch the largest medical association in Ireland, and there is a balance in hand of over £20 The following were elected office bearers for the ensuing year —President Professor T Sinclair Vice-Presidents Dr W D Donnan (Holywood) and Dr A. B Mitchell (Belfast). Council Country—Dr J C. Martin (Portrush) Mr G L St. George (Lisburn), Dr J Stuart (Ballymena) Dr D Gausson (Dunmurry) Dr Darling (Lurgan) Dr J O Hall (Monaghan), Dr S. Agnew (Lurgan) and Mr R. Gray (Armagh), City of Belfast—Sir W Whitla, Dr A Dempsey Dr C. E. Shaw Professor J A. Lindsay Dr John Campbell Dr H L. McKisack Professor J W Byers, and Dr T S. Kirk. Representative of the branch on the Parliamentary Bills Committee Dr Dempsey Representatives of the branch on the Central Council of the British Medical Association Professor Byers and Dr W Calwell Treasurer Dr G Gray (Newcastle). Secretary Dr Calwell.—Dr Shaw showed a case of Paralysis of Convergence.—Dr V G L. Fielden read a short paper on Anaesthesia by Gas and Oxygen in General Surgery which was criticised by Dr Mitchell Professor J L Smith and Professor Byers.—Mr H. N Barnett read notes on Some Unusual Cases of Small pox.—Dr Dempsey read notes of two cases in which the uterine appendages were removed for Inoperable Cancer —Mr Kirk read notes of Obscure Abdominal Symptoms following Ruptured Kidney and he showed three Calculi removed from the urethra and a Vermiform Appendix removed on the day of the meeting —Professor Byers gave an account with clinical details of an abdominal section for an unusual Tumour of the Ovary—a soft spindle celled sarcoma. He also showed a Fibro-myoma of the Broad Ligament weighing 26 pounds, which apparently is the third largest tumour of this nature published as having been successfully removed Microscopic sections of both tumours, prepared by Dr R J Johnstone, were exhibited —Dr Calwell showed (1) Convenient Forms for the Subcutaneous Administration of Sterile Gelatin and of Sterile Glucose Solution (2) a specimen of Malignant Disease of the Stomach and (3) Skiagrams of Pulmonary Tuberculosis. He also read notes of a case of Intermittent Glycosuria the presence of sugar being induced by bouts of alcoholism.

Presentation to Dr Daniel Murphy

On July 19th the senior students of the Cork North Charitable Infirmary assembled in the board room for the purpose of making a presentation to the late house surgeon Dr Daniel Murphy as a token of the high esteem in which he was held during the two years that he was connected with them The presentation took the form of a midwifery bag with fittings complete. On the outside of the bag was an engraved plate bearing the inscription, Presented to Daniel Murphy M B by the senior students of the North Charitable Infirmary July 12th 1902." The students having assembled Mr D D Donovan, senior physician was on the proposition of Mr C Baylor seconded by Mr E. Walsh unanimously voted to the chair Mr Donovan having thanked the students for the honour which they had done him in asking him to make this presentation said that it was a pleasure to be asked to preside on the occasion —Dr Murphy replying said that he looked back with pleasure on the happy time he had spent in the North Infirmary and that he would always prize the gift which the senior students had so thoughtfully presented to him —The proceedings terminated with a vote of thanks to Mr Donovan proposed by Dr W F O Connor (house surgeon) and seconded by Mr Baylor The students were afterwards entertained by Dr Murphy

July 22nd

PARIS

(FROM OUR OWN CORRESPONDENT)

New Suggestions for Meals in Hospitals

M CHAUFFARD recently laid before the Hospital Medical Society certain suggestions concerning the meals served to patients in the hospital Up to now *déjeuner* has been at 11 o clock and dinner at 5 o clock. M Chauffard would not interfere with the former meal but wishes to put the dinner later He also suggests that instead of all the patients eating in bed those who are able to be up should dine in a refectory separate from the wards. Those who have to be in bed should be provided with a little table to be placed on the bed. Meals too should be served hot and not be allowed to get cold as they are at present M Chauffard complains in addition about the soup meat (*bouilli*) and the soup (*bouillon*) Soup should only be made he considers from those portions of meat which are of no use for anything else. Desiccated vegetables served as a *purée* should be largely used and as many kinds of fresh vegetables as possible should be given care being taken to see that they are of good quality Another reform which he is anxious to see carried out is to give every patient a bottle full of fresh water At present, if a patient wishes to get water to mix with his wine he has to get up and fetch it for himself from the tap

The Medical Students Union.

Five hundred medical students have just founded an association in defence of their interests, both moral and material The association will not deal with any political questions. The first meeting was held on July 7th in the large theatre of the School of Medicine and the promoters of the movement read out the provisional regulations. The objects of the association were defined as follows to find out and to put into practice the most useful methods for the moral development of the profession to transmit to the proper authorities the decisions arrived at by medical students in their general meetings so long as these decisions have to do with scholastic or professional matters to facilitate by every possible means professional instruction among the members and to bring about the strongest possible bonds of union between medical men professors, and medical students. These suggestions were unanimously approved Other matters discussed were the admission of representatives of students in every Faculty to the University Council and admission without fee to practical studies. Another question which was much discussed was whether foreign students should be admitted to the association. At present the headquarters of the new association are in some buildings in the Boulevard St. Michel which the students of the School of Pharmacy have kindly placed at the disposal of their medical brethren.

The Lille Faculté Libre of Medicine

An important judgment has just been given at Lille The law states that *facultés libres* of medicine cannot be founded unless they have at their disposal 120 beds in a hospital either founded by themselves or else placed at their disposal by the Assistance Publique In 1875 the Catholic faculties of Lille made a convention with the Lille hospitals by which the latter in consideration of the sum of 140 000 francs handed over to the *Faculté Libre* of Medicine two blocks containing 200 beds, a theatre and a post-mortem room. All these buildings were in the St Eugénie Hospital which was then in course of building and they were handed over for an unlimited time. The Prefect approved the transaction but his approval was not endorsed by the Minister concerned The State Council however declared that as the scheme had been entered upon the Minister had no power to annul the decision of the Prefect. Last year a majority of the members of the Hospital Committee came to the conclusion that they would demand the annulment of the agreement Accordingly the Mayor of Lille, as President of the committee haled the governing body of the Catholic faculties before the civil court Judgment has now been given and the Hospital Committee is non suited

The Self sacrifice of Dr Garnault

On Tuesday June 17th a Paris physician Dr Garnault inoculated himself with bovine tuberculosis with a view to test the correctness of Professor Koch s statement that bovine tuberculosis is not communicable to human beings. The experiment was undertaken in the abattoirs at Villette in the presence of three colleagues of Dr Garnault On the previous evening Dr Garnault had blistered the anterior surface of his left forearm On the Tuesday morning the epidermis was cut away from the blister and the raw surface was slightly scratched A tuberculous gland was taken with aseptic precautions from a tuberculous cow and having been reduced to pulp in a mortar was applied to the raw surface by means of a pad and bandage. It was allowed to remain in contact for the space of two hours The result of this experiment was that recently some small red papules appeared at the site of inoculation which are taken to be cutaneous tuberculides No infection of glands has appeared and Dr Garnault who is anxious that such infection should be manifested, determined not to await its development from the first inoculation but has proceeded to carry out another experiment. On July 15th he, in the laboratory of Dr Barlerin, placed in the subcutaneous cellular tissue of his forearm a portion of a tuberculous nodule taken from the liver of a tuberculous cow which had that morning been killed in the abattoir Microscopic examination of a portion of this nodule showed masses of the bacillus tuberculosis The wound in the skin was sutured aseptically and Dr Garnault hopes in a little time to be in a position to state whether Koch is right or wrong in affirming that bovine tuberculosis is non transmissible to human beings

July 22nd

NEW YORK

(FROM OUR OWN CORRESPONDENT)

The Automobile in the United States

THE automobile has gained for itself a very bad name in America among the community at large. In New York the craze for automobiling has become an intolerable nuisance and also a source of grave public danger Not a week passes but the papers contain an account of some fatality due to the automobile and generally sad to relate, owing to the carelessness of the *chauffeur* or to the fact of the machine being driven at a very high rate of speed The people of the United States are much given to boasting of the freedom of the country, but when this freedom takes the form of trampling upon the rights of other citizens it is hard to say where the advantage of it comes in Freedom too often is allowed to degenerate into licence here, and in no country have private rights to be preserved by such incessant struggle as in the United States The owners and drivers of automobiles have too long been allowed flagrantly to disregard the rules of the road, for although a few traversers of the law are arrested occasionally, the punishment meted out to them seldom or never is in proportion to their offence The limit of speed should be rigidly fixed and offenders should be punished heavily for contravening this regulation Again, such portentous evil smelling machines as some of the large racing automobiles should not be allowed on city streets. Gaudy, noisy, and malodorous, they are a terror alike to pedestrian and horse and have greatly helped to render the already crowded and bustling streets of New York an abomination to the nervous citizen Many automobilists have exhibited so cynical an indifference and so brutal a disregard for the rights and feelings of the remainder of the population, that the only resource is to make them conscious of their error by severe punishment , otherwise it is seriously to be feared that members of the public will take the law into their own hands and that regrettable scenes of violence will ensue

Radio therapy in Cancer and Skin Diseases

Dr Charles Warrenne Allen, professor of dermatology in the New York Post-Graduate Medical School, read recently before the New York County Medical Association a paper on the above subject, in which he reported 28 cases where the use of the x rays had been attended with more or less success Referring to the question of focus tube dermatitis and burns, Dr Allen said that he did not designate such injuries as x ray burns because he was not thoroughly convinced that it was the x ray *per se* which produced the effect. He believed that the popular dread of those so called burns and the importance attached to them in radio therapy by physicians have been over estimated Dr Allen's conclusions were as follows That the method is one of decided value. But that it is not without its disadvantages and the injudicious or careless use of it may lead to its being brought into disrepute. It is not a method likely to supersede, or to do away with, all previous methods, but it has its decided place of utility The method appears to be of utility in recurrent cancers. If it proves as valuable as present indications promise there is no reason why it should not be applied to primary cancer He advises the medical man not to pave the way to disappointment by promising himself or his patient too much from this new method There is, in the opinion of Dr Allen, no contra-indication to the employment of other forms of treatment coincidently The most favourable time to treat cancer, by the ray or otherwise, is early At this stage the majority of cancers can probably be cured When cancer has passed beyond a certain stage it does not differ from tuberculosis in its probable fatal result

Magnesium Dioxide

A discovery which is said to be of some therapeutic importance has been made recently by Dr Frederick Elias of Berlin He has succeeded in obtaining pure magnesium dioxide, MgO_2, which is capable of liberating a large amount of diffusible oxygen, it is said, throughout the system. Magnesium dioxide occurs as an impalpable white powder, tasteless, odourless, non astringent, non irritant, non toxic, and is insoluble in water According to analysis it is free from barium, strontium, or calcium compounds It contains no sodium dioxide or caustic potash and therefore it possesses no caustic properties It is further said to exude large quantities of diffusible, readily assimilable oxygen The valuable therapeutic qualities which it is asserted this preparation possesses are that it exerts very beneficial remedial and curative effects in the treatment of those diseases arising from deficient oxidation and characterised by alteration of the blood corpuscles or by a qualitative deficiency of the blood itself

July 13th

Obituary.

EDOARDO PORRO

A VALUED correspondent in Italy writes —"Sectio Caesarea salubrior instituta," such is the "title-deed to fame," such the service to humanity recorded on the all too early grave of this consummate obstetrician and gynæcologist Born at Padua, of Milanese parents, on Sept. 17th, 1842, Edoardo Porro began his professional studies at the university of his native town and after graduating with great distinction became assistant to more than one of his teachers in the departments of medicine and surgery In 1866 the war between Italy and Austria for the possession of Venetia called him to the Trentino to serve under Garibaldi , and again in the following year the cry of his chief, "O Roma, o morte" (Rome or death), brought him, a prompt and ardent volunteer, to the battle fields of Monterotondo and Mentana, where the issue, disastrous for the time to the revolutionary cause, yet led, by "historical necessity," to the culmination of Italian unity with Rome for the capital.

From this brief but glorious episode he again threw himself into professional work and in the December of 1868 we find him assistant physician at the Scuola di Ostetricia of the provincial hospital of Santa Caterina under Professor Pietro Lazzati, in the August of 1870 assistant-in chief in the same school, and in the March of 1871 successor to Lazzati as director—a post which he held till the November of 1872, when he was appointed consultant obstetrician to the Opera Pia of Santa Corona. Here he remained till 1875, so perfecting himself in the department which had now become his specialty that when the chair of obstetrics fell vacant in the University of Pavia he was at once chosen to fill it, thence, on Nov 1st, 1882, rising to the post of his ambition, that of director and consultant-in-chief of the Scuola Ostetrica of Milan His clinical activity was prodigious, his pen barely keeping time with the results of his acute exhaustive observation and swift generalising power Already, to the May number of 1871 of the *Annali Universali di Medicina*, we find him contributing a striking paper entitled, "Sopra un Caso Singularissimo di Patologia Embriologica," quickly followed by others entitled, "Sopra un Caso di Obliterazione Congenita dell' Esofago" and "Risultati Apparenti e Risultati Veri del Parto Prematuro Artificiale"—the latter paper attracting attention and discussion throughout the whole gynæcological world In February, 1872, he dedicated to his colleagues his masterly narration of "Un Caso Clinico dell' Aborto provocata per Grave Ristrezza Pelvica da Osteomalacia," initiating a regular campaign, professional and lay, in vindication of the rights of science against dogmatic prejudice Operations, described in contributions to the journals, continued to succeed others with almost breathless rapidity till on May 21st, 1876 he startled the world with his amply and impressively illustrated memoir, "Della Amputazione Utero-Ovario, come Complemento del Taglio Cesareo," describing the operation, as original as it was daring with which his name will be perennially associated. This memoir translated into the principal contemporary languages, led to the practice of the operation by leading obstetricians of the day a practice so successful that it has undoubtedly wrought the salvation of thousands of human lives. In Italy alone, Mangiagalli, Truzzi Bertazzoli to mention only a few followed on the lines of the master with almost unvarying success and a quarter of a century afterwards as recorded in THE LANCET[1] at the time, the gynæcologists of all countries combined in celebrating the first jubilee of the operation presenting its author with an illuminated address and coining in his honour a medal bearing the inscription with which this obituary notice begins

Porro's later years were less prolific in literary though quite as rich in clinical activity—one cause of this being the multiplication of the offices which he held offices civic and municipal among others to which the respect and confidence with which his citizens honoured him inevitably led up He wrought indefatigably for the rehabilitation of the Istituti Ospitalieri' of Milan while for the Ospedale Maggiore he drew up a complete plan of reforms with a view to enhance the efficiency of that venerable and renowned institution. Frequently summoned as an expert before the legal tribunals he upheld the just claims and the dignity of science while extorting from the forensic side the amplest acknowledgments of his judicial fairness and chivalrous urbanity In sympathy with the freest handling of religious themes his attitude towards traditional Christianity on the one hand and aggressive Naturalism on the other was that of Mr A. J Balfour's 'Foundations of Belief"—an attitude which kept him on the friendliest terms with Mystic and Agnostic, with Catholic, with Protestant, and with Free thinker alike His will just made public, is a characteristic attestation of his convictions religious political and social, and it is quite in keeping with the simplicity of his life that we read his expressed wish that his funerali should be *modestissimi senza fiori, senza partecipazioni personali.*

He was" says a contributor to the *Secolo* of Milan 'a victim to duty In performing an operation on an unfortunate woman infected with the male Celtico he wounded his hand. From that day he never succeeded in expelling from his system the fatal poison which manifested itself in diverse viscera, eventually setting up a nephritis, followed by crises of the most alarming kind His strength declined steadily uræmic poisoning became only too apparent, whilst the proximate cause of death on the 16th inst. was an attack of pulmonary œdema which every effort failed to overcome Telegrams of sympathy and condolence have already reached the family from leading gynæcologists many of them pupils all the world over and the sorrow of the Milanese public is giving his funeral a touchingly impressive character which even his testamentary dispositions have been powerless to countervail

HENRY MARTYN JORDAN F R.C S. ENG L.R.C P LOND

MR. H. M JORDAN died at his father's residence, The Knoll Newport, Mon on July 14th from pneumonia which he contracted while on a visit.

Mr Jordan received his medical education at Guy's Hospital taking the qualifications of L R.C P Lond and M R.C.S Eng in 1889 and being admitted to the F R.C.S Eng in 1892. After holding several resident appointments at Guy's Hospital he was appointed lecturer on anatomy and surgery at H.H. the Nizam's Medical School Hyderabad Deccan On his return to England in 1896 Mr Jordan practised in Weymouth-street, London and at the time of his death he was surgeon to the Westminster General Dispensary Mr Jordan formerly took a great interest in football and had represented Wales in several international matches in 1884 and 1889 The deceased who was only 37 years of age was unmarried.

DEATHS OF EMINENT FOREIGN MEDICAL MEN —The deaths of the following eminent foreign medical men are announced —Dr Wilhelm Kiesselbach extraordinary professor of otology in the University of Erlangen.—Professor Gerhardt of Berlin whose name will be remembered in connexion with the ca e of the Emperor Frederick.

Medical News.

The diploma of the society was granted to the following candidates entitling them to practise medicine surgery and midwifery:—B. C Curtis, H. G Daft S F Hickman G W C Hollist E A. Houchin T G Miles, C Millauro G Roper T Scatchard J E Skey H. H Sloane, and H. C S Woodward

THE ROYAL DENTAL HOSPITAL OF LONDON CONVERSAZIONE.—A very successful social evening was spent in the Royal Institute Galleries Prince's Hall Piccadilly on Friday July 18th, 1902, by the staff, students and friends of the Royal Dental Hospital of London on the occasion of the prize distribution Sir Arthur W Rücker D Sc. LL.D F R.S. principal of the University of London, presented the prizes to the successful students. The dean in offering a hearty welcome to Sir Arthur Rücker gave a short sketch of the progress of the hospital and school, and it was decided to send a message of loyalty to the King and an expression of thankfulness for His Majesty's restoration to health and of gratitude for the honour which he had recently conferred upon the institution by desiring it to be called a Royal hospital. An excellent programme of music and other entertainments was provided.

HOSPITAL SATURDAY IN DEVONPORT —July 19th was observed in Devonport and Stonehouse as Hospital Saturday The factory employés of the Keyham and Devonport dockyards have a separate organisation with a hospital committee of their own and they annually contribute about £180 to the Royal Albert Hospital but the Hospital Saturday Fund proper averages less than £240 and as £160 of this sum are contributed equally by the firm and men of Sir John Jackson (Limited) the total sum raised by all the remaining working men of Devonport and Stonehouse is only £80 This is a ridiculously small sum and it is to be hoped that the amount raised this year will be largely in excess of the previous years.

THE HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S PARK.—Presiding at the annual meeting of the Hospital for Epilepsy and Paralysis, held for the first time at the new building in Maida Vale the President the Earl of Hardwicke referred to the fact that had it not been for a large and unexpected bequest that building must have stopped short at the ground floor as the committee had wisely determined at one time that it must do. To equip the first section of the new hospital £2500 would be required and for this sum the President made an earnest appeal with the view of enabling the committee to utilise the fine building now requiring only to be fitted and furnished. The adoption of the annual report was seconded by Canon Duckworth and the re-election of the retiring members of committee was moved by Sir Owen Tudor Burne.

NOTES ON CURRENT TOPICS

Midwives Bill

THE amendments made in the Midwives Bill by the House of Lords were taken into consideration by the House of Commons on Monday July 21st, and were one and all accepted The Bill therefore awaits the royal assent before becoming law

HOUSE OF COMMONS

WEDNESDAY, JULY 16TH

Notification of Infectious Disease in Ireland

Mr FIELD asked the Chief Secretary to the Lord Lieutenant of Ireland whether he would consider the advisability of introducing a Bill this session to assimilate the law regarding the Infectious Disease (Notification) Act 1869, and the Infectious Disease (Prevention) Act 1890, in Ireland and Great Britain so as to make notification compulsory by urban or rural sanitary authorities in Ireland —Mr WYNDHAM replied A Bill has been drafted on the lines suggested by the question I am prepared to bring it in but could not undertake to find time for any but the briefest discussion

THURSDAY, JULY 17TH

Poor-law Medical Officers and Operations

Dr FARQUHARSON asked the President of the Local Government Board whether he would explain why, under regulations of the Local Government Board, no provision whatever had been made for the administration of anæsthetics when operations had to be performed by Poor law medical officers on sick paupers at a distance from a hospital or workhouse infirmary, and why no alteration had been made in the scale of fees allowed for special operations performed by Poor-law medical officers since the year 1847, many important operations, which had now become general not having been added to the original list.—Mr LONG replied The first matter referred to in the question has been dealt with by the Local Government Board by means of a circular letter which they issued to boards of guardians in November 1894 In that letter the Board recommended that under ordinary circumstances a case in which a serious operation was required should not be treated in a workhouse or at the patient s home but should be sent to a public hospital They stated however, that in any case when the latter course was not practicable or when the operation was not of a serious character they were prepared if an anæsthetic was required, to consider an application from the guardians for sanction to the payment to the medical officer of a reasonable sum in respect of any assistance which it was necessary for him to obtain in connexion with the administration of the anæsthetic or of other cost incurred in connexion with its use It has been the invariable practice of the Board to give their sanction to reasonable payments proposed to be made by boards of guardians to medical officers in circumstances of the kind referred to I am not aware that difficulties have been experienced in connexion with the scale of fees to Poor law medical officers for operations but if representations are made to me showing that alterations are required I shall be willing to give the subject careful consideration At the same time I would repeat that under ordinary circumstances cases requiring serious operations should not be treated in a workhouse or at the patient s home but should be sent to a public hospital

THE MEDICAL SERVICE OF THE ARMY

In Committee of Supply on the vote of £1,025 000 for the medical establishments of the army

Colonel WELBY urged the War Office to see that the medical service of the army was maintained in proper strength and efficiency

Mr H. C RICHARDS called attention to the practice of requiring several signatures before medical stores could be obtained in time of war for those who needed them, and advocated the introduction into the system of a little practical common sense

Mr BRODRICK said that in this connexion immense progress and immense amelioration had taken place within the last few years The House of Commons had done good service in calling attention to the weakness of this part of the administration of the army and he would remind the House that it had allowed him to make a great addition to the medical establishments He could only say that he believed the system now set on foot which had involved his asking Parliament for a large number of extra medical officers with a considerable increase of pay and provision for classes and study leave and other things would bring the Army Medical Service into line with the best civilian practitioners of the day

Major JAMESON insisted that the condition of things in the Army Medical Service was still far from satisfactory and recommended the department to offer employment to the civilian doctors who had come to the assistance of the army during the war

Colonel WELBY asked for an answer to this definite question—whether in the future it would be possible for the War Office by a stroke of the pen to transfer a medical officer from one army corps to another

Sir JOHN BATTY TUKE said that he could not but think that certain of the hon Members who had spoken were not aware of the important steps taken by the Secretary for War to reorganise the Army Medical Service. They had gone back in the past and there was a great temptation for one who had followed the history of that service from the Crimean war down to the present time to do the same But he was content to refrain from doing so as far as possible as he believed the scheme now at work was a whole hearted attempt to reform the service and to do justice to the army medical officers He begged to congratulate the right hon gentleman on the adoption of a new administrative principle All previous Ministers for War had proceeded on the assumption that they could work the machine independently of the great medical schools and the feeling of the medical profession at large As a consequence all previous attempts to reform the service had failed mainly, though not entirely from the non recognition of the principle Not entirely for failures had also been due to maladministration of former warrants and retrocessions on the part of the War Office in carrying out their provisions That the right hon gentleman had become convinced of the necessity of recognising this principle was shown by the fact that of the 11 members of the committee appointed by him in 1901 to consider the reorganisation of the medical service seven were civilians all men who were connected with important medical schools, and by the further fact that on the advice of that committee an Advisory Board had been established four of the members of which were civilians He begged to congratulate the Minister for War on the establishment of this principle, notwithstanding that he could not agree with him entirely on the manner in which he had applied it. The first objection was that it would be impossible for these four gentlemen to perform all the duties which were laid upon them The board was to meet at fortnightly intervals to report on all matters connected with medicine surgery and sanitation as they affected the military services to advise on the provision and equipment of hospitals to submit a scheme for the expansion of the service to meet the needs of war, to report on plans for hospitals barracks and camps to arrange for the annual inspection of each of the military hospitals such inspection to be usually made without notice; to supervise the examinations of candidates and to consider the promotion of officers How was it possible for men in active practice to perform such multifarious duties for a mere pittance of £200 year? It was impossible and it would be found in practice that these four gentlemen could only have referred to them special points for their advice and consideration This would be a most important function for them to perform but that they could carry out all that was imposed on them by the report was impossible Further he wished that the hon gentleman had carried out the special recommendation of Sir William Thomson who did such excellent work in South Africa He as a member of the committee in a minority report recommended that the Advisory Board should be composed of representatives of the medical schools in the several divisions of the kingdom. The Secretary for War had accepted this principle as regards Ireland and England but had evaded it so far as Scotland was concerned It was true that he had appointed a gentleman in London who held a Scottish degree but had no other connexion he had lived all his life in London, could in no way represent the feeling in Scottish schools or adequately represent the genius of the country and had not had any connexion with military matters It consisted with his knowledge that the Secretary for War took a great deal of trouble to secure a practitioner resident in Ireland and that he never once entered into communication with anyone connected with Scotland or in any way consulted the feelings of the schools of that country He might ride off on the statement that of the military members of the Advisory Board two or three were Scottish graduates Such an argument was futile as these gentlemen had lived their lives in the service and could not be *en rapport* with professional feeling in the North The Secretary for War might as well argue that because the Prime Minister and the leader of the Opposition were both Scots the electoral representation of Scotland was on an equable footing with that of Ireland It should be remembered that about one-third of the medical recruits came from the North which afforded the highest class of candidates He was not arguing this from a mere provincial point of view It was impolitic to ignore and flout these great schools When they came to consider that any scheme for the expansion of the service must depend on the assistance provided by universities, schools and hospitals it was evidently a wise policy to keep in close touch with teaching institutions on which must depend to a great extent any scheme for an Imperial Medical Reserve. The establishment of an Imperial Medical Reserve must be a chief object to be kept in view by the Secretary of State It was impossible to keep up a standing medical force during times of peace sufficient for the sudden emergencies of war This was one of the lessons we had learnt from the late war The Army Medical Service must be made capable of rapid expansion and this could only be effected by appealing to civilians. This was not the time to propound a scheme for the establishment of such a body but it might be said with certainty that the War Office would have to come to the teaching institutions of the country and demand their assistance in formulating a scheme by which a system of units could be established ready to act under any emergency Under these circumstances it would have been more politic for the Secretary for War to do everything in his power to maintain the *entente cordiale* with important centres of medical education What they did in haste during the late war must be provided for at leisure As to the new Royal Warrant he would have liked to have spoken at more length but he saw other medical members present who might desire to speak He believed it would work well The pay was fair the system of examination for promotion was sound It would do much to prevent slackness and would give an opportunity for the better men to show what they were made of In every service there were two curses—seniority and private influence. If the system of examination were made to exercise its due influence if it were taken along with each man s service record it would serve a most important function in neutralising those curses But it must also be remembered that the thorough working of the new warrant would depend on the maintenance of the Royal Army Medical Corps at a proper level The arrangements for leave and study leave could not be worked unless the service were numerically sufficient. The warrant might easily break down in many of its most important provisions if the service were starved But in the hope that no retrocessions would occur, as they had occurred as regards previous warrants he begged to congratulate the Secretary for War upon the earnest effort he was making to produce a really efficient service

Dr FARQUHARSON said that while in former days those in charge of the affairs of the army had tried to legislate for the medical service without reference to the class from which the members of that service must be drawn he thought he saw in the regulation now issued by the Secretary of State a sincere desire to take into his confidence the great medical schools and teaching bodies in order to get terms which might be acceptable to them and to those whom they taught He frankly acknowledged that in the new warrant there were important and valuable alterations In fact, the new warrant would make things much more acceptable to the medical profession generally and he believed that it would end in this—that a large number of students would come to the service In his opinion the terms now offered were, on the average very favourable They were very different from those offered 20 years ago when he entered the service As to the late war his opinion was that in no former war had the general results of medical and surgical treatment been so successful, and he thought the Army Medical Department was entitled to great credit for those results. He congratulated the Secretary of State on making the Director-General of the Army Medical Department a member of the new Army Board He was not quite so sure about the new Advisory Board. He was not quite so enthusiastic as the last speaker about the inclusion of the civilian element He thought that the old plan was a good one of having a director general with three or four subordinates each taking up a particular department of work, and all combining to discuss questions from the purely medical point of view He hoped however that the new arrangement might be found to work well Though he did not wish to appear in a critical mood, he was bound to say that he thought the remuneration was rather small On behalf of the medical profession he thanked the right hon gentleman for his admirable warrant which he believed would bring peace and contentment to the Army Medical Department and which he sincerely hoped would establish better relations with the great medical schools and cause a steady flow of their very best candidates to the service. He would like the right hon gentleman to explain the exact situation of the new hospital which was going to be started in London for army medical officers and what relation it would bear to the hospital at Netley

Mr BRODRICK said that he was unable to answer the hon member specifically because the new arrangements in London had not yet been absolutely completed, though he was pressing forward the matter as fast as he could He was glad to hear what the hon. member had said because he had received the report of a speech delivered some time ago by him in Scotland in which he denounced the scheme for the reorganisation of the Army Medical Service as a total failure in all respects. He thought that the scheme had in the main greatly commended itself to the medical profession Of course there would be criticisms and these he would be glad to have but the immense change which had been made by introducing civilian members to the Advisory Board was a change which he believed to be of the greatest benefit to the army His hon friend (Sir John Batty Tuke) read out the long list of subjects with which the Board had to deal He admitted that it was a long list, but he thought that the business-like character of the work done its thoroughness and efficiency and the time which these medical gentlemen themselves in large practice were giving to the public service were things which the army and the public had not sufficiently recognised Nothing that they could give them would be enough to compensate them for the time and patience which they had expended in the service and he thought that they had the greatest reason to be grateful to them He did not think that the Board could have worked more admirably He knew that it was about to undertake the inspection of the hospitals on the lines laid down As to the constitution of the Board he confessed that his hon friend had forestalled his line of argument It was quite true that in selecting a Scottish graduate he was not able to contemplate asking the leading man of the Scottish profession to attend in London, but he rather set himself to get a man of ability and experience in London who could give regular attendance to the work of the board But in reality Scotland had nothing to complain of for nearly one-half of the Advisory Board were Scottish graduates He assured his hon friends that there was every desire to act as thoroughly as they could not merely with the London medical schools but with the provincial schools and the Scottish and Irish and colonial schools. The change had had one remarkable effect already: up to last year they had not been able to fill their vacancies or to obtain a sufficient number of candidates of adequate standing In the last few days the result of the general improvement and the increase of confidence on the part of the medical profession had been such that for the 33 vacancies there were between 70 and 80 candidates He was quite certain that nothing would be wanting on his part to increase this confidence He attached the greatest importance to the arrangements which they were making for study leave and for the training of officers during intervals of their service. They had adopted for the medical service what was practically the short service system. If a man joined the medical service and after three or four years experience did not like it, then he could return to civilian life He believed that the other proposals such as trying to attach a medical officer to a unit at the beginning of his service and thus giving him a sort of home and providing against those too frequent moves which had had an irritating effect would all contribute to the popularity and efficiency of the service. It was impossible yet to see the results of the reform but he felt great confidence in the future. They had had a most favourable start. He was well aware that they had errors to make good—errors of knowledge and experience—but in these as in other respects they had taken to heart the lessons of the war and he was very sanguine that those who followed him would see that whatever else had been done for the army during his administration at all events a long step forward in this important service had been taken

Mr RICHARDS asked whether the right hon gentleman intended to continue the system under which several signatures were required before a dying man could get the medical comforts he needed. He said that a salary of £100 a year was altogether inadequate for the civilian members of the Advisory Board

Mr BRODRICK said that the best proof he could perhaps offer that the very best men in the medical profession had given their services to this most important work was that among the number were Sir Frederick Treves and Mr Fripp He could make no statement off hand as to what was required in the way of signatures He should never dream of keeping things from people who required them but he would remind his hon. friend that in time of war stores must be carefully husbanded

Colonel WELBY moved a reduction in the vote of £100 in order to elicit from the Secretary of State an answer to his question.

Mr BRODRICK said that he was perfectly ready to answer the question The whole Royal Army Medical Corps with the exception of a very few officers, had been engaged in South Africa and at the present moment they had to rely to a large extent on civilians for the different stations at home Therefore the new system had not yet got into working and until they could bring medical officers home in large numbers, which he hoped would be soon it could not be put in force

Colonel WELBY said that what he wanted to know was whether by a mere stroke of the pen an army doctor could be moved from one army corps to another

Mr BRODRICK said that they had got a new Director-General who had established a variety of changes, and his scheme had not yet been put in operation, and therefore he could not at present answer the question

Major JAMESON asked whether the right hon gentleman would take steps to have the old forms for requisitions altered

Mr BRODRICK replied that he was perfectly willing to undertake that fuller attention would be given to the simplification of these forms

The motion for the reduction of the vote was withdrawn and the vote itself was agreed to.

FRIDAY JULY 18TH

London Water Question

The House devoted practically the whole of its sitting to the consideration in Committee of the London Water Bill An attempt was made to raise the question of the ruling of Lord Balfour of Burleigh in the Joint Committee but the Chairman decided that it was not competent for the House of Commons to criticise the action of a member of the House of Lords. The first clause of the Bill was still under discussion when the adjournment took place

MEDICAL OFFICER REQUIRED FOR PERTH (WESTERN AUSTRALIA) FRIENDLY SOCIETIES' MEDICAL INSTITUTE 126 MURRAY STREET, PERTH

To the Editors of THE LANCET

SIRS —In several provincial papers advertisements have appeared for a medical man for the above vacancy applicants to seek information from a firm of advertising contractors St Bride's-street E C There is evidently considerable difficulty in getting an Australian or local man Intending applicants should read the rules and conditions very carefully Rules 20 and 23 (as samples) are worth repeating Candidates may know what kind of gentlemanly treatment they will receive and what ks they run in taking an appointment of this kind

Rule 20 Should the medical officer through illness be unable to orm his duties he shall obtain the services of a qualified practitioner Should he decline or neglect the committee shall *punish him* by suspension and he shall have no claim upon the institution save only to date of appointment being cancelled

N B —Is the practitioner expected to send to this country for a *locum tenent?*

Rule 23 is no less interesting The medical officer shall treat every member or his family who may apply for advice with civility He shall not detain them any time so as to give them cause to complain bearing in mind that every individual is paying his share and has a right to *immediate attendance*

I am Sirs, yours faithfully

July 23rd 1902. M.B B S

*** If all the rules of this institution are such as our correspondent quotes we should certainly advise all practitioners to refrain from applying for the post —ED L

CRYPTORCHISM

To the Editors of THE LANCET

SIRS —A man aged 28 years consulted me about a pain extending from a point about an inch in front of the scrotum up to the right loin coming on directly after intercourse with his wife They had been married about two months and his wife was aged 30 years She thought there might be something *wrong* with her but on examination I found all normal but not so with the husband The left side of the scrotum contained what I thought might be a wasted testicle but only like a little thickened skin and the right side was quite empty and no testicle could be made out in the canal I presume therefore that the organ is still in the abdomen and that the vas deferens is absent or impervious I cannot find a record of such a case as regards the pain and I could only express a hope that an outlet might be gradually forced My hope however is only slight and the question is what is best to be done in such a case I fear pain &c., may lead to mental trouble If through the medium of THE LANCET I can get any information I shall be very thankful

I am Sirs yours faithfully

July 22nd 1902. ENQUIRER

THE DUTIES OF A MEDICAL MAN

To the Editors of THE LANCET

SIRS —A married woman has contracted syphilis I have not seen her husband for some months and am not aware that he is under treatment for any complaint. The patient ought to be warned of her contagious condition If I tell her she will probably (and possibly with justice) accuse her husband as being the cause If I tell the husband privately and not the patient he may accuse her of infidelity, either justly or possibly with the object of shielding himself Kindly advise me what I should do I am, Sirs yours faithfully,

July 21st 1902. BETA

*** Our correspondent's duty is in the first place to prevent the spread of disease Clearly the husband ought to be warned of the risks that he runs in continuing marital relations if he is not already infected The wife had better be told that in her condition sexual connexion is not permissible for medical reasons, and the husband must be informed of the true state of the case —ED L

"HAS YOUR HAIR BEEN COMING OFF?'

WE take the following paragraph from the *St James's Gazette* of July 21st :—

> At Bow street police-court to-day an elderly woman applied to Mr Marsham for advice She said that some time ago her 'young man lodger" stole one of her buck rabbits and placed it in his own hutch in which he kept a doe Mr Marsham Well, what was the result? The Applicant Nine little rabbits your worship (Laughter) Mr Marsham That is very satisfactory The Applicant Yes but he only wants to give me one as my share Mr Marsham That is not a bad offer I suppose your rabbit has not suffered at all? The Applicant Yes, it has It's taken all the hair off its back The magistrate directed an officer to interview the lodger with a view to effecting an amicable arrangement between the parties

The falling of the hair is a common symptom in an equally common disease, and the question with which we have headed this note is very frequently asked in out-patient rooms As however, the lower animals are probably immune from the disease in question we have every hope that the "nine little rabbits" will not develop snuffles'

THE "Y" FUND

SURGEON GENERAL H S MUIR begs thankfully to acknowledge additional donations towards the above Fund from Mrs R Hackett Major Carew, D S O (7th Hussars), Major F Wyville Thomson, I M S., Captain W Rothney Battye, I M S Mr Ormiston (Hong Kong) Colonel and Mrs W McWatters R.A.M C, Lieutenant-Colonel and Mrs P J McQuaid, R.A.M.C Lieutenant-Colonel and Mrs Haywood R.A M C, and the following officers of the Royal Army Medical Corps Lieutenant Colonels G A. Hughes D S O P J Dempsey, and H. Charlesworth, C M.G Majors M J Whitty S F Clark H H Brown, and J J C Watson C I E, Captains W F Ward and H G F Stallard and Lieutenant F P Lander The fund now amounts to £448. It may be explained that this is in response to an appeal made privately to members of the profession for benevolent aid in a distressing case which has been described in a letter sent to a limited number of medical men (who would help the cause by kindly ' handing on to *confrères*) Should any reader of THE LANCET desire further particulars with a view to expressing *practical sympathy* a copy of the letter will be forwarded on application to Surgeon General Muir 26 Kensington gardens-terrace Hyde Park, London W

RAMIE" UNDERCLOTHING

THIS material is described as consisting of the fibres of a species of plant of the Boehmeria genus It forms at the same time a firm, crisp and elastic thread for the substance of a garment for the skin The fabric is extremely porous while protective It is remarkable in showing no stains due to perspiration even when worn during the hot weather The material does not set up any irritating action upon the skin and is comfortable and cool to wear It does not obstruct perspiration but encourages its distribution and at the same time it conserves the normal warmth of the body Under the microscope the nature of the fibre was made clear, We received specimens of this material from Messrs Hall, Nilsen, and Co of 47, Mosley street Manchester

SATURDAY (2nd).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES

THE INDEX TO THE LANCET

THE Index to Vol. I. of 1902, which was completed with the issue of June 28th, and the Title-page to the Volume, were given in THE LANCET of July 5th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1902 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Presidential Address

ON

MANCHESTER'S EARLY INFLUENCE ON THE *ADVANCEMENT OF MEDICINE AND* MEDICAL EDUCATION

Delivered at the Seventieth Annual Meeting of the British Medical Association

By WALTER WHITEHEAD, F.R.C.S., F.R.S. EDIN.,

PRESIDENT OF THE ASSOCIATION; CONSULTING SURGEON TO THE ROYAL INFIRMARY, MANCHESTER.

[MR. WALTER WHITEHEAD commenced his address by bidding the Association welcome to Manchester He then referred to the fact that when the Association last visited Manchester 25 years ago the medical school had just amalgamated with the Owens College and this day July 29th' said Mr Whitehead "is the fifty sixth anniversary of the death of John Owens. Mr. Whitehead then referred to those now gone from us who had taken an active part in the former Manchester meeting Esau Wilkinson, the President Lund and Bradley two eminent surgeons Leech the pharmacologist, Sir William Roberts the first Professor of Medicine in the Owens College, and Thorburn the gynæcologist. After a reference to the arrangement of the work of the meeting Mr Whitehead reminded his audience that Manchester began to increase in size and in wealth in about the middle of the eighteenth century and that it was at about that date that many of the great Manchester institutions came into being With reference to the Royal Infirmary he continued —]

Charles White and the Royal Infirmary

Of the institutions for the benefit of the people which came into being at this epoch let me speak first of the Royal Infirmary on account, not only of its intrinsic importance—it was at once a general hospital an isolation hospital for infectious diseases and a hospital for lunatics—but also because it played indirectly a great part in the intellectual activity of this city Moreover it is probably the oldest of our public institutions for it had its first beginning just a century and a half ago when Charles White with the financial assistance of Joseph Bancroft, a man conspicuous for his public and private charities" hired and fitted up a small house in Garden street, off Shude-hill now a wilderness of warehouses. It would seem that it only required the stimulus supplied by Charles White's enthusiasm to convince the leading inhabitants of the then small but growing town of the need of a hospital, for within a couple of months of this modest beginning a conference was held and a committee appointed to collect money Their first step was to purchase from Sir Oswald Mosley the lord of the manor the Daub Hole Field"[1] a site of a little over an acre and it is on this field and some adjoining land acquired subsequently that the infirmary still stands. A west wing forming the first part of the infirmary buildings was taken into use in 1755 and provided beds for 40 patients

Ten years later a wing was added for the reception of patients suffering from mental diseases. At that time only three such institutions existed in the country the hospitals of Bethlem and St. Luke in London and the institution at Newcastle-on Tyne. The patients in the lunacy block of the infirmary were placed under the supervision of the physicians to the infirmary and this arrangement continued until 1847 when partly to provide more beds for the infirmary proper and partly because the building was found to be out of date, the mental cases were removed to the Manchester Royal Lunatic Hospital at Cheadle, now under the able direction of Mr G W Mould, the lecturer on mental diseases in the Owens College. In 1796 another addition was made to the infirmary by the erection of a separate building in the infirmary grounds to receive patients suffering from infectious fevers this also was officered by the physicians to the infirmary, but as I shall have to refer to it again it will suffice to say that the arrangement continued until 1870 when a special hospital was erected at Monsall For a time the city authorities defrayed the cost of patients for whom they were responsible, but eventually purchased the hospital which now provides in detatched blocks, accommodation for 400 patients who are under the charge of the medical officer of health and his colleagues As a consequence of these and other changes the accommodation provided by the infirmary proper was steadily increased until it now contains beds for 292 patients while its capacity is indirectly increased by the convalescent home at Cheadle which accommodates 136 convalescents and by further provision for the reception of such patients in institutions at Southport and Buxton.

The name of Charles White appears first on the list of surgeons to the infirmary He was the son of Thomas White who was appointed a surgeon extraordinary what we should now call a consulting surgeon, at the same time. Charles White was born in 1728 and spent his boyhood in Manchester in the earliest period of that remarkable outburst of intellectual activity in which he was himself to bear no mean part. He studied medicine in London where he was the friend and fellow student of John Hunter and after his return to his native city he quickly won great distinction as a surgeon and an obstetrician. He was one of the earliest of conservative surgeons for he removed the head of the humerus for caries in 1768, was the first to excise the shoulder joint, and proposed excision of the hip in 1769 He was famous also as a lithotomist and his use of dry sponge to arrest hæmorrhage foreshadowed the sponge-grafting suggested not many years ago by Professor Hamilton. As an obstetrician he did much to place the obstetric art on a sound basis, and along with his son and the two Halls (Edward, his colleague at the infirmary and Richard) he founded the Manchester Lying in Charity now St. Mary's Hospital. In 1773 he published a treatise on the management of pregnant and lying in women which went through many editions and was translated into German, he also wrote a most excellent treatise, likewise translated into German on phlegmasia alba dolens. He formed no doubt under the influence of the example of his friend John Hunter an anatomical museum which, when offered to the infirmary in 1806, contained some 300 specimens. The museum eventually became the property of the Lying in Hospital but was unfortunately for the most part destroyed in a fire which occurred in 1847 His interests extended beyond purely professional subjects for he was one of the founders of the Manchester Literary and Philosophical Society and one of its first vice presidents. He was a friend of *De Quincey who in his autobiography gives a personal* sketch of the great surgeon of the north. White seemed to have had some inkling of the theory of evolution, for in 1799 *he contributed* an essay on the Regular Gradation in Man and in Different Animals and Vegetables and from the former to the latter In his later days he was much interested in forestry and wrote a book on the subject. He was a great tree planter at his country house near Sale and died there at the age of 85 years

From its earliest days the infirmary which was honoured with the title of Royal in 1830 has rendered great services to Manchester and the surrounding district and to the progress of medical and surgical science. At first as I have said it had beds for 40 patients In 1811 the number of beds had increased to 71 and as 932 patients were admitted in that year each bed was used on the average by 13 patients In 1848 the number of beds had increased to 182 and the number of patients admitted to 1713, so that there was an average of nine patients to each bed in the course of the year In 1901 the number of beds was 292 and the number of patients admitted was 4446, an average of over 15 patients to each bed. Thus during the last half century the number of patients benefited has increased much more rapidly than the number of beds This fact may I think be accepted as striking evidence of the advance of medicine and surgery and of the increased efficiency of treatment and administration within the infirmary itself. This conclusion is confirmed by the examination of some statistics which

---

[1] Dr F Renaud believes that the field was so called because from it was obtained the clay for the wattle and daub of which most Manchester houses of the sixteenth and seventeenth centuries were constructed In an oblong excavation made by the removal of the clay water collected and from this infirmary pond, as it came to be called the thrifty inhabitants drew their water-supply at the time of the foundation of the infirmary and for long afterwards. It was indeed, not finally emptied until 1840 when the Waterworks Company pumped it dry at the request of the Commissioners of Police for the public benefit

Presidential Address

ON

MANCHESTER'S EARLY INFLUENCE ON THE ADVANCEMENT OF MEDICINE AND MEDICAL EDUCATION

Delivered at the Seventieth Annual Meeting of the British Medical Association

BY WALTER WHITEHEAD, F.R.C.S., F.R.S. EDIN.,

PRESIDENT OF THE ASSOCIATION; CONSULTING SURGEON TO THE ROYAL INFIRMARY MANCHESTER.

[MR. WALTER WHITEHEAD commenced his address by bidding the Association welcome to Manchester He then referred to the fact that when the Association last visited Manchester 25 years ago the medical school had just amalgamated with the Owens College and this day July 29th, said Mr Whitehead ' is the fifty sixth anniversary of the death of John Owens." Mr Whitehead then referred to those now gone from us who had taken an active part in the former Manchester meeting Evan Wilkinson the President Lund and Bradley two eminent surgeons Leech, the pharmacologist Sir William Roberts the first Professor of Medicine in the Owens College and Thorburn the gynæcologist. After a reference to the arrangement of the work of the meeting Mr Whitehead reminded his audience that Manchester began to increase in size and in wealth in about the middle of the eighteenth century and that it was at about that date that many of the great Manchester institutions came into being With reference to the Royal Infirmary he continued —]

Charles White and the Royal Infirmary

Of the institutions for the benefit of the people which came into being at this epoch let me speak first of the Royal Infirmary on account, not only of its intrinsic importance—it was at once a general hospital an isolation hospital for infectious diseases and a hospital for lunatics—but also because it played, indirectly a great part in the intellectual activity of this city Moreover it is probably the oldest of our public institutions for it had its first beginning just a century and a half ago when Charles White with the financial assistance of Joseph Bancroft, a man conspicuous for his public and private charities, hired and fitted up a small house in Garden street, off Shude-hill now a wilderness of warehouses. It would seem that it only required the stimulus supplied by Charles White s enthusiasm to convince the leading inhabitants of the then small but growing town of the need of a hospital, for within a couple of months of this modest beginning a conference was held and a committee appointed to collect money Their first step was to purchase from Sir Oswald Mosley the lord of the manor the Daub Hole Field [1] a site of a little over an acre and it is on this field and some adjoining land acquired subsequently that the infirmary still stands. A west wing forming the first part of the infirmary buildings was taken into use in 1755 and provided beds for 40 patients.

Ten years later a wing was added for the reception of patients suffering from mental diseases. At that time only three such institutions existed in the country the hospitals of Bethlem and St. Luke in London and the institution at Newcastle-on Tyne. The patients in the lunacy block of the infirmary were placed under the supervision of the physicians to the infirmary and this arrangement continued until 1847 when partly to provide more beds for the infirmary proper and partly because the building was found to be out of date, the mental cases were removed to the Manchester Royal Lunatic Hospital at Cheadle, now under the able direction of Mr G W Mould, the lecturer on mental diseases in the Owens College. In 1796 another addition was made to the infirmary by the erection of a separate building in the infirmary grounds to receive patients suffering from infectious fevers this also was officered by the physicians to the infirmary but as I shall have to refer to it again it will suffice to say that the arrangement continued until 1870 when a special hospital was erected at Monsall For a time the city authorities defrayed the cost of patients for whom they were responsible, but eventually purchased the hospital which now provides in detatched blocks, accommodation for 400 patients who are under the charge of the medical officer of health and his colleagues. As a consequence of these and other changes the accommodation provided by the infirmary proper was steadily increased until it now contains beds for 292 patients, while its capacity is indirectly increased by the convalescent home at Cheadle which accommodates 136 convalescents and by further provision for the reception of such patients in institutions at Southport and Buxton.

The name of Charles White appears first on the list of surgeons to the infirmary He was the son of Thomas White who was appointed a surgeon extraordinary what we should now call a consulting surgeon, at the same time. Charles White was born in 1728 and spent his boyhood in Manchester in the earliest period of that remarkable outburst of intellectual activity in which he was himself to bear no mean part. He studied medicine in London where he was the friend and fellow student of John Hunter and after his return to his native city he quickly won great distinction as a surgeon and an obstetrician He was one of the earliest of conservative surgeons, for he removed the head of the humerus for caries in 1768, was the first to excise the shoulder joint, and proposed excision of the hip in 1769 He was famous also as a lithotomist and his use of dry sponge to arrest hæmorrhage foreshadowed the sponge-grafting suggested not many years ago by Professor Hamilton. As an obstetrician he did much to place the obstetric art on a sound basis, and along with his son and the two Halls (Edward, his colleague at the infirmary and Richard) he founded the Manchester Lying in Charity now St. Mary's Hospital. In 1773 he published a treatise on the management of pregnant and lying in women which went through many editions and was translated into German, he also wrote a most excellent treatise likewise translated into German on phlegmasia alba dolens. He formed no doubt under the influence of the example of his friend John Hunter an anatomical museum which when offered to the infirmary in 1806, contained some 300 specimens. The museum eventually became the property of the Lying in Hospital but was unfortunately for the most part destroyed in a fire which occurred in 1847 His interests extended beyond purely professional subjects for he was one of the founders of the Manchester Literary and Philosophical Society and one of its first vice-presidents. He was a friend of De Quincey who in his autobiography gives a personal sketch of the great surgeon of the north. White seemed to have had some inkling of the theory of evolution for in 1799 he contributed an essay on the Regular Gradation in Man and in Different Animals and Vegetables, and from the former to the latter In his later days he was much interested in forestry and wrote a book on the subject. He was a great tree planter at his country house near Sale and died there at the age of 85 years.

From its earliest days the infirmary which was honoured with the title of Royal in 1830 has rendered great services to Manchester and the surrounding district and to the progress of medical and surgical science. At first, as I have said it had beds for 40 patients In 1811 the number of beds had increased to 71 and as 932 patients were admitted in that year each bed was used on the average by 13 patients. In 1848 the number of beds had increased to 192 and the number of patients admitted to 1713, so that there was an average of nine patients to each bed in the course of the year In 1901 the number of beds was 292 and the number of patients admitted was 4446, an average of over 15 patients to each bed. Thus during the last half century the number of patients benefited has increased much more rapidly than the number of beds This fact may I think be accepted as striking evidence of the advance of medicine and surgery and of the increased efficiency of treatment and administration within the infirmary itself This conclusion is confirmed by the examination of some statistics which have been taken from the records of the infirmary at a considerable cost in time and trouble by my friend, Mr W L Saunder, who has grown grey in his devoted service to the interests of the infirmary, and Mr Charles Roberts, the present resident surgical officer Mr Saunder finds that for the year ending June 24th, 1879 (the earliest for which such data are now available), the average period of occupation of a surgical bed—that is to say, the average period each surgical patient was under treatment—was 24 57 days In 1901 the average period for which each surgical patient was under treatment had sunk to 18 1 days

---

[1] Dr F Renaud believes that the field was so called because from it was obtained the clay for the wattle and daub of which most Manchester houses of the sixteenth and seventeenth centuries were constructed In an oblong excavation made by the removal of the clay water collected and from this infirmary pond as it came to be called the thrifty inhabitants drew their water-supply at the time of the foundation of the infirmary and for long afterwards It was indeed not finally emptied until 1840 when the Waterworks Company pumped it dry at the request of the Commissioners of Police for the public benefit

I regret that I have no comparable figures for the medical wards, but that there has been a marked improvement all round as compared with half a century ago is shown by the fact that a rough calculation discloses that whereas in 1848 the average period for which each patient admitted to the infirmary, taking medical and surgical together, was under treatment was 41 days, the average period in 1901 was not quite 24 days The other statistics have reference to the results of operations Dr Renaud tells us that in 1839-40 the number of operations performed was 143 with 36 deaths—that is to say, one operation in four was followed by death In 1878 the number of recorded operations was 337 but it must be remembered that the number of beds had been increased Now Mr Charles Roberts finds that in 1901 the number of operations had increased to 2652.[2] I suspect that some of my medical friends are saying that these figures afford an awful example of the "lust for operation" as to which we have heard recently But that this is not so and that my surgical colleagues on the active staff were fully justified in what they did is shown by the results, for of the 2652 patients operated on 2544 recovered and only 108 died—that is, only about one operation in 24, or 4 07 per cent, was followed by death Moreover, an examination of the list of all deaths after operation in 1901, which has been prepared for me by the resident surgical officer, shows that in a large proportion probably more than half, they were desperate cases, in which the accident was so severe, or the disease so serious or extensive, that operation could afford only the slenderest hope of recovery [3]

Mr Crossley's Gift to the Manchester and Salford Hospital for Consumption

If I may be allowed to include Salford and Ancoats as parts of greater Manchester then I must add a few words as to the two other general hospitals—the Salford Royal Hospital and the Ancoats Hospital. The first had its origin in 1827 and the corner-stone of a portion of the present building was laid in 1830, though it was not until 1845 that 10 beds were provided for in patients It was gradually enlarged until it contained 62 beds in 1882, in which year my old friend, the late Mr John Pendlebury, bequeathed a sum of money which enabled the governors to increase the number of beds to 127 The Ancoats Hospital grew out of a dispensary for out and home patients founded in 1828 in the interests of the working classes then becoming concentrated in the district and with the view of relieving the pressure upon the infirmary A large part in this movement was taken by the late Sir James Kay Shuttleworth who had settled in Manchester as a physician in 1827 and early turned his attention to public health questions, though he found time to publish in 1834 a treatise on the physiology, pathology, and treatment of asphyxia which won for him the Fothergillian medal of the Royal Humane Society The Ardwick and Ancoats Dispensary grew into a general hospital, the first stone of which was laid in 1871 A new pavilion, the gift of Mr James Jardine, raising the number of beds to 114, was opened in 1888 by the then Prince of Wales, now King Edward VII, whose rapid recovery from a serious illness under the skilful treatment of my friend Sir Frederick Treves may justly be reckoned among the triumphs of modern surgery

I have already referred incidentally to some of the other hospitals in Manchester, and I should have liked to introduce here some account of the foundation and growth of St. Mary's Hospital, the Eye Hospital, the Children's Hospital, and other institutions which are doing good work, but time warns me to hurry on I cannot, however, leave this part of the subject without some reference to the munificent gift of my friend, Mr W J Crossley, to the Manchester and Salford Hospital for Consumption and Diseases of the Throat. The hospital was founded mainly through the exertions of the late Dr J Shepherd Fletcher, at one time lecturer on anatomy and secretary of the Medical School in Chatham street, and of Dr Alexander Hodgkinson, lecturer on diseases of the larynx in Owens College. The admirable investigations of our able medical officer of health, Dr J Niven, have shown that in Manchester, as in other cities, the prevention of this "white plague" presents us with a problem calling for strenuous efforts Thanks to the epoch making discovery of Koch, we now know that consumption is a preventable disease, subsequent investigations of this master of experimental pathology and of many other skilful workers, among whom I would mention as one of the most original and successful Dr Sheridan Delépine, Procter professor of pathology in this college, have placed us in possession of facts which show us the nature of the methods by which the scourge may be diminished and perchance in time extinguished Chief among these is the prevention of the infection of healthy persons The open air treatment of consumption takes the sufferer in the early stage of his illness, places him under conditions of life which have been proved to favour his cure, and thus gratifies the generous pity which impels us to help the sufferer and enables us at the same time to fulfil the duty which we owe to the community to prevent others from contracting the disease In order to place this system of treatment within reach of the poorer citizens of Manchester and Salford Mr Crossley is building, on a site comprising 66 acres at Birch Hill, in Delamere Forest, 420 feet above sea level, a sanatorium where 80 sufferers from consumption will find every means for their recovery which experience can devise or generosity provide. The erection and equipment of the sanatorium will cost the donor some £70,000 The best way in which the people of Manchester can show their gratitude to him is to respond freely to the appeal which the Lord Mayor has made for subscriptions to a fund for the endowment of the institution which Mr Crossley's public spirited munificence has provided

Manchester Medical Schools

In Manchester, as in other communities full of active life, the development of the medical school was not along one smooth continuous path The work of many men, sometimes along paths apparently divergent, was necessary, but, as in every process of organic evolution, there were times of rapid accretion with succeeding periods of absorption, leaving an organism fit for steady and sturdy growth Amidst all the struggles and rivalries, which extended over nearly half a century, there was evolved a school of which Manchester may well be proud and the true value of which to the community will rise as the union between the college on the one hand and the infirmary on the other becomes more intimate. So far as medical education is concerned these two institutions must be regarded as one, with common interests and joint duties towards the community in and for which they work, for of the science and art of medicine it may truly be said that it is nothing if not practical and that in all his active work the practitioner of the art must be guided by a kind of sublimated common sense.

We owe, I believe, the first beginnings of a medical school in Manchester to Charles White, the founder of the infirmary, for in 1786, assisted by his son, he began a course of lectures on anatomy and physiology, while Thomas Henry gave a course of lectures on chemistry concurrently Henry, who had become a visiting apothecary to the infirmary in 1778, was one of the founders of the chemical industry in this district The son of an Antrim man who had settled as a schoolmaster at Wrexham, he first practised as an apothecary at Knutsford After a few years he removed to Manchester, where he continued his medical practice, but he had already become deeply interested in practical chemistry and in 1771 communicated to the Royal College of Physicians of London an improved method of making magnesia alba Acting on the advice of his friends he began the manufacture of this substance, whence he got the name of "Magnesia Henry," and this business was most successful. He was one of the founders of the short-lived College of Arts and Science and lectured there not only on theoretical chemistry but also on such technical subjects as bleaching dyeing and calico-printing He was an authority especially on dyeing and also wrote on ferments and on the value of lime and marl as manures He was a friend of Priestley and translated the physical and chemical essays of Lavoisier with whom and with other foreign investigators he had been brought into correspondence by his experiments on fixed air (he observed that carbonic acid gas, so far from being injurious, was actually beneficial to plants) He wrote a memoir of Haller whose career is sketched in the very recent work entitled "Some of the Apostles of Physiology" in which my friend Professor Stirling has given an account of the lives and labours of those who have contributed to the advancement of the healing art as well as to the prevention of disease Henry was one of the founders and the first secretary of the Literary and Philosophical Society Later he became its President and held that office at the time of his death in 1816. His son who was physician to the infirmary was a friend of Davy and Wolaston and a chemist of considerable eminence. He was the author of the earliest text-book of experimental chemistry and more than a century ago lectured on the application of chemistry to arts and manufactures. When coal gas was introduced as an illuminant he was among the first to study its constitution to lay down rules for analysis, and to indicate the means by which it might be purified. I may here digress to observe that Mr John Leigh the first medical officer of health of Manchester before his appointment to that office in 1868 had given much attention to the subject of the analysis of illuminating gas, and as early as 1842 communicated to the British Association which met that year in Manchester an account of the mode of preparation of nitro-benzole a discovery turned to good account by those who more fortunately shortly afterwards founded the aniline dye industry

---

[2] Of these 1774 were performed by the honorary staff and 878 by the resident staff The latter number includes cases from the out patient department and the accident room

[3] The operations followed by death may be roughly classified as follows for cancer 20 for sarcoma 6 trephining, 10 (for fracture of the skull, 7 for complications of otitis media 3) tracheotomy 10 laparotomy 19 (for gastric ulcer 6 for intestinal obstruction or stricture 6 for ruptured spleen 1 for perforated appendix 1 gastrotomy for œsophageal stricture 1 cholecystotomy 1 peritonitis 1) herniotomy for strangulation or obstruction 8 for radical cure of hernia 4 drainage of appendicular abscess, 2 for urethral stricture 3 for compound fracture of long bones, 4, miscellaneous, 22

I do not know whether the lectures given at the infirmary by the Whites and Henry were largely attended. I suspect not, for regular pupils were admitted to the practice of the infirmary for the first time in 1793. Lectures indeed do not seem to have been given systematically though in 1796 Mr Benjamin Gibson commenced a course, illustrated by demonstrations of the specimens collected by Charles White then preserved in a museum at the corner of King street and Cross-street, the site of the present Reference Library Gibson gave special attention to diseases of the eye and wrote on the Formation of an Artificial Pupil on the Extraction of Soft Cataracts and on the Use of the Couching Needle in Infants of a Few Months Old [4] an operation in which he appears to have been very expert. It makes us realise the benefits which anæsthetics have conferred on mankind to be told [5] that when Mr Gibson operated upon the eyes of young children they were really put into a sac that had an eyelet with a cord through it which was fastened round the child's neck and by this means the youngsters were much more easily controlled by the assistants.'

John Jordan's School of Anatomy

Dr Ferriar Dr Roget, Mr Ainsworth, and Mr Ransome the father of Dr Arthur Ransome, whose early work in Manchester in connexion with the prevention of tuberculosis is happily continued with increasing effect to the present day also took part in the courses given at the infirmary but we must, I think assign to Mr Jordan the honour of being the real father of the Manchester Medical School He was born in 1787 and commenced the systematic teaching of practical anatomy in Manchester He was assisted by Dr Hull physician to the Lying in Hospital and a botanist of distinction, and by Mr Brigham. It was the day of small things and Jordan and his colleagues began their school with four students. The course was practical from the first. As this was in the days before the Anatomy Act the acquisition of subjects for dissection must sometimes have been a difficulty But whatever his difficulties Jordan overcame them and in 1817 his certificates of instruction in anatomy were recognised by the Society of Apothecaries of London Jordan was an enthusiastic anatomist and it is related of him that a medical friend who called upon him once when he was ill espied a set of bones under the bed which Jordan said he found it convenient to keep at hand that he might distract himself by their study Where Jordan's pupils first dissected I am not certain, but the earliest references I have traced place the school in Back Queen street, off Deansgate nor am I aware whether courses in other subjects of a medical education were given there.

Thomas Turner and the Royal Manchester School of Medicine and Surgery

Manchester however was not to wait long for a complete medical school, its foundation was due to the energy of Mr Thomas Turner a remarkable man who during his life of 82 years accomplished a great work for medical education He was born at Truro in Cornwall in 1793, was apprenticed in Bristol was a pupil of Sir Astley Cooper at the old borough hospitals of Guy's and St Thomas's and came to Manchester in 1817 as house surgeon to the infirmary He afterwards settled in private practice in Manchester and in 1822 gave a course of lectures on human anatomy physiology and pathology before the Manchester Literary and Philosophical Society Encouraged by the interest shown in these lectures he put forth two years later a scheme for a school of medicine and surgery It was started in a house in Pine-street and John Dalton one of the most illustrious names in the intellectual history of Manchester gave the lectures on pharmaceutical chemistry The enterprise was immediately successful and in the following year the staff was thoroughly organised, lectures on medicine being given by Dr afterwards Sir James Bardsley on surgery by Mr Ransome on midwifery by Mr Kinder Wood and on botany by Mr Thomson. Dalton continued the lectures on pharmaceutical chemistry while Turner took anatomy physiology and pathology Clinical experience could be gained in the infirmary with its dependent lunatic asylum and fever hospital at the Lying in Charity the Eye Hospital and the Lock Hospital Turner was justly proud of the ample opportunities for dissection which he was able to offer to his pupils and boasted that in this respect the Manchester school was superior to those of London and Edinburgh. The school was recognised in 1825 as a fully equipped medical school by the Royal College of Surgeons of Edinburgh and I am therefore able to claim for it the honour of being the oldest, as it is still I believe, the largest, of the great provincial medical schools of England. It was recognised in 1827 by the medical departments of the army and navy The Council of the Royal College of Surgeons of England which was then controlled by surgeons connected with certain metropolitan hospitals, proved more obdurate. In 1828 however a slight concession was made as a consequence of the report of a committee of the House of Commons on the teaching of anatomy before which Turner gave evidence The certificate of instruction in anatomy of the Pine-street School was then recognised. As a result of an inquiry held by another committee of the House of Commons in 1834 on Medical Education the exclusive policy of the Council of the Royal College of Surgeons of England with respect to the reception of certificates of instruction required from candidates for its examinations was at last abandoned, and the Pine-street School was placed on the same footing in respect to the clinical teaching of its students as the great schools in London Dublin Edinburgh Glasgow and Aberdeen. The relations between the Manchester Memorial School and the Royal College of Surgeons of England have long been of a cordial kind Mr Turner and Mr Lund were long members of its Council My friend Mr Hardie has only just retired from that office, and the Conjoint Board of the Royal Colleges of Physicians of London and Surgeons of England has recently arranged that in future the first professional examination shall be held simultaneously in London and at the Owens College, as the centre most convenient for students of the medical schools in the northern counties of England.

The Manchester Medical School possessed as early as 1834 a chemical laboratory a dissecting room, a library and museums of anatomy pathology and materia medica The keystone to the structure of medical education which Turner and his friends were building up had been placed in 1833 when regular courses of clinical lectures were commenced at the infirmary The first course was given by Dr Carbutt who lectured once a week from the beginning of June to the end of December and it has been preserved in a volume which in its form did great credit to the taste of the Manchester printers of that date [6] The substance shows Carbutt to have been a shrewd, well read, and thoughtful physician and a man of an independent turn of mind. The motto on his title page is the Horatian line—

[6] Clinical Lectures in the Manchester Royal Infirmary by Edward Carbutt, M D Manchester 1834

> 'Nullius addictus jurare in verba magistri."

He shows himself a strong partisan of the theory that very many diseases—from chorea to diabetes—are due to what is now called autotoxæmia and to be cured by forms of depleting treatment, which to us in the present day seem to be "methods of barbarism" Nevertheless, his patients appear to have recovered in fair proportion and with reasonable speed, and I have no doubt that the students learned much of practical value from his teaching, for he very wisely made no selection of cases but spoke on each one as it came under observation, so that he had many opportunities of dealing with the more common diseases

Other Medical Schools in Manchester

The Pine street School was not the only one established in Manchester about this time. I have already mentioned the School of Anatomy started by Mr Jordan, this was expanded in 1827 into a School of Medicine in Mount-street, by the institution of courses of lectures on chemistry by Mr Davies, on medicine and materia medica by Dr Freckleton, on surgery by Mr Fawdington and Mr Boutflower, and on midwifery by Mr Radford, while Mr Jordan, who lectured on anatomy, was assisted by Mr Blundstone and Dr Pritchard Hulme, who gave demonstrations in that subject. In 1834 Mr Jordan retired and most of the lecturers joined a new school founded in that year in Marsden street It only lasted six years, for it was closed in 1840, and its library was presented to the Royal Manchester School of Medicine in Pine street. This school remained without a rival until 1850, when some of the lecturers at the Marsden street School joined with Mr Southam, Mr Dumville, and Dr Watts in founding a school in Chatham street Mr George Southam was the moving spirit, he was the secretary of the school and lectured on surgery He was surgeon to the Royal Infirmary and possessed an abundance of sound common sense and surgical acumen. He was an active member of this Association and was President of the Council from 1871 to 1873 When the medical department of Owens College came into existence in 1872 he was appointed the first lecturer on surgery and in the following year professor He died in 1876, but his son, who is now senior surgeon to the infirmary, worthily follows in his father's footsteps The school in Chatham street was only continued for eight years, when it was absorbed by the Royal Manchester School, which had steadily been growing in importance and had already entered into the negotiations which led eventually to its transformation into the medical faculty of the Owens College The success of the school founded by Thomas Turner had indeed been signal, and Jordan paid a generous tribute to the importance of the achievement, all the more striking when it is remembered that it was altered by a rival. 'The establishment of provincial medical schools," he wrote, "was of national importance and was one of the movements of the age Indeed, there has not been so great a movement since the College of Surgeons was established." Turner, who founded the school in 1824, became surgeon to the Royal Infirmary in 1830, lived to see the amalgamation with the Owens College and give the inaugural address at the first session of the medical faculty He died in 1873 and his connexion with the College is commemorated by the Turner scholarship in medicine and surgery Jordan died in the same year at the age of 87 years.

Early Schemes for a University College in Manchester

It may fairly be claimed for the medical school, which during the latter years of its independent existence bore the honourable title of the Royal Manchester School of Medicine and Surgery, that it had a large share in bringing about the foundation of a university college in Manchester, for in 1836 Mr Thomas Turner and his colleagues put forth a plan for a college, with faculties of arts and medicine, to be connected with the University of London, which had then recently undergone one of its periodical reorganisations In the same year an alternative plan for a university for Manchester, first proposed in 1789, was revived by a paper read by Mr Harry Longueville Jones before the Manchester Statistical Society This paper was printed as a pamphlet at his own expense by Mr James Heywood, F R S, who declared in an address to the Manchester Athenæum that a university college was not only wanted but actually called for in Manchester For various reasons, into which I need not now inquire, neither scheme was at that time successful, yet these discussions of the educational needs of Manchester, though they ended apparently only in the disappointment of the hopes of the public spirited men who took part in them, were yet destined at no distant date to bear fruit The idea of founding a college for Manchester free from the restrictions then imposed by the Test Acts at Oxford and Cambridge grew in the mind of John Owens, and, fostered by the enthusiasm of George Faulkner, his partner in business, led to the foundation of the Owens College and eventually to the creation of the Victoria University

The Owens College

The schemes of Turner and his friends and rivals, which eventually became embodied through the benefaction of John Owens, were not indeed the earliest for the establishment of a college for higher education in Manchester. More than two and a half centuries ago Manchester, in 1641, presented a petition to the Long Parliament asking for a charter for an independent university, but the opposition of York, which urged that it had better claims to be the seat of a northern university, brought the scheme to naught. A College of Arts and Sciences was founded in 1783 and in 1786 came the Manchester Academy which, after a career marked by many vicissitudes, now finds a home in Oxford as Manchester College. Its short life in Manchester was perhaps memorable chiefly because it was the means of bringing to our city John Dalton who, in 1793, left his native Kendal to become its professor of mathematics and natural philosophy In Manchester he ever after resided, resisting some tempting offers to establish himself elsewhere Of the epoch-making work which he did there, especially his researches into the laws which govern the physics of gases this is not the time or the place to enter, but I may recall to you that his essay on colour blindness, a defect from which both he and his brother suffered, was communicated to the Literary and Philosophical Society of Manchester in 1794 It was the first detailed description of that curious condition which still bears his name, though the term Daltonism is more often met with in foreign than in British publications—one more example of how true it is that in Great Britain, as in Judæa, a prophet is not without honour save in his own country

Dalton, as I have already said, was one of the first lecturers at the School of Medicine in Pine street, and in truth his wide interest in all scientific inquiries and speculations brought him often into contact with questions having a bearing on medicine As an example may be mentioned his researches in meteorology They also were communicated to the Literary and Philosophical Society and were among the earliest in which accurate methods of investigation were brought to bear on that perplexing science Again, one of his earliest studies, while yet he lived in the Lake District, which he ever loved, was botany, and he used to form collections of dried plants, from the sale of which he gained money to help his own education in other directions. It is said, indeed, that he first became aware of the defect in his appreciation of colours by discovering that he was unable to distinguish flowers by their colours as others could He was a member of the Society of Friends and a man of simple life and somewhat austere character It is related of him that when, late in life, he was persuaded to be presented at Court, he only consented to don a doctor's gown because he could not perceive its brilliant hue. His many sided scientific interests are commemorated in the Owens College by scholarships or prizes in mathematics, chemistry, and natural history, and the Society of Friends has given his name to the hall of residence, open to all denominations, which they established in 1876 for the benefit of students of the Owens College. His most illustrious pupil was James Prescott Joule who carried out in Manchester all those remarkable researches on the conservation of energy and on the mechanical equivalent of heat which belong to the very groundwork of modern science and have profoundly affected our conceptions of the order of the universe He never as far as I can ascertain held any office in the Owens College, yet it might have been expected that so illustrious a man of science would have been commemorated in the science faculty of the College of the city in which he lived and worked, but I know of no scholarship or prize bearing his name. The total amount of John Owens's benefaction was under a hundred thousand pounds, a small sum for the achievement of so great an object as the founder had in view The success which has attended the foundation has been due in large measure to the wise conception which the founder had formed of what a university college should be. He conceived of it rather as a body of men, teachers and taught than as a building of bricks and mortar and directed that the endowment should be devoted to the provision of an adequate teaching staff. In a hired house, then, to which a chemical laboratory under the direction of Edward Frankland had been added the Owens College opened its doors in March, 1851. At first its success by no means fulfilled the expectations of its friends, but the conception was right and slowly for a time but with ever increasing rapidity during the last 40 years, it has drawn to itself not only many students in all faculties, not only munificent gifts and bequests from Manchester men but also other organisations working in Manchester in the interests of higher education. Thus in 1872 the fine collections formed by the Manchester Natural History Society and the Manchester Geological Society were transferred to the College and formed the nucleus of the Manchester Museum now displayed in the buildings which form the northern part of the main front of the College. The museum has from the first been conducted on broad lines and contains valuable collections illustrating the sciences of zoology and botany ethnology and anthropology mineralogy and geology In 1872, also when the Royal Manchester School of Medicine was incorporated with the Owens College, the Manchester Medical Society brought to it its library of 13,000 volumes, which has since grown to 32,000 volumes

There physic fills the space, and far around
Pile above pile her learned works abound;
Glorious their aim——"

The collection, I believe, deserves all that the poet wrote in praise of a medical library and little of what he said in criticism of medical books although we may to-day perhaps still find a parallel here and there to the practitioner thus described a century ago —

One to the gout contracts all human pain
He views it raging in the frantic brain
Finds it in fevers all his efforts mar
And sees it lurking in the cold catarrh."

What the library owes in respect to the value and number of its volumes, to the indefatigable exertions of Mr Thomas Windsor has never been fully appreciated save by a few of his most intimate friends who know that in the zenith of his career as a most successful oculist he abandoned altogether his practice and devoted his life to the collection and study of rare medical and scientific books The general collection of books belonging to the College numbers over 70 000 volumes and is contained in the fine Christie Library building on the south side of the quadrangle presented by Mr Richard Copley Christie for 15 years a professor in the College The foundation of John Owens, broad in its conception though small in its beginnings has grown with the growth of Manchester and with the increased love of knowledge and learning until it is now one of the greatest educational institutions in the country It has erected a fine pile of buildings containing halls and lecture rooms, libraries and laboratories, where instruction may be obtained in every department of knowledge and, more than that, where opportunities are afforded to those who show aptitude for original inquiry to search out fresh secrets from Nature and to apply the new knowledge thus gained for the benefit and elevation of mankind. For 30 years the medical students of Manchester have had the advantages of receiving in its lecture rooms but still more in its laboratories the training in those ancillary sciences which they must study before they can enter with profit upon their special technical education and also in those fundamental departments of the body of medical knowledge so happily termed in the Scottish universities the institutes of medicine. Within its walls, by the kindness of the College council rooms have been provided for all the 17 sections while the general meetings are held in this beautiful Whitworth Hall which commemorates the name of one of the most munificent benefactors of the College. The medical faculty has steadily grown in number and importance since it first formed part of the Owens College In 1872-73, when the amalgamation took place the medical students constituted 28 45 of all those studying within the College. In 1883-84 the proportion rose (excluding the women's department) to 40 8 per cent. and in the last two years to over 42 per cent.[7]

It was, I think the added strength brought to Owens College by the great medical department acquired by this amalgamation which emboldened the Senate to seek university powers In 1875 a draft scheme for the enlargement of the College into a university was published by Professor Greenwood, Sir Henry Roscoe, Professor A. W Ward, and Professor J E. Morgan. Mr Joseph Thompson, in his history of the Owens College, has declared that it is to the zeal and untiring devotion of these four gentlemen that Manchester owes its university others cordially supported the movement, but they through five weary years, placed their case before the public, removed prejudices advanced good arguments, and lived down opposition' Professor Morgan argued the case from the medical side, he showed that of the 14 000 practitioners in England in 1874 only 28 per cent. were graduates of medicine, and that of this 28 per cent. 20 per cent. had obtained their degrees in Scotland He pointed out that while there were 11 medical schools in London and eight in the provinces, only four universities—Oxford, Cambridge, Durham and London—had the right of conferring degrees in medicine and adduced weighty reasons in favour of founding a new university in the North of England. He pointed out that such a university should be situated in a populous town connected with a large hospital with a suitable medical school possessing well-appointed laboratories and an efficient staff of professors and lecturers, and that finally it must give guarantees that teaching rather than the sale of degrees would be its great object, these conditions, he urged, Owens College and Manchester could supply In 1877 a deputation which had the support of the late Sir Henry Acland regius professor of medicine in the University of Oxford, asked the then President of the Privy Council, the Duke of Richmond and Gordon, to confer on Owens College the rank of a university with the title of the University of Manchester The proposal was at first opposed by the authorities of the Yorkshire College Leeds but eventually the differences were adjusted and on June 30th 1879 it was announced that the Crown had been advised to grant a charter to a northern university to be called the Victoria University Owing however to opposition from medical authorities and teachers in other places the charter eventually granted on April 20th, 1880, creating the Victoria University and constituting the Owens College a college therein contained a clause which held back the right to confer degrees in medicine Two years later the Royal Commission on the Working of the Medical Acts recommended that the power to grant its own medical degrees should be given to the Victoria University without delay and in 1883 a supplementary charter removed the restrictions. It was thus due entirely to the efforts of the Senate, Council, and Court of Owens College that a northern university with its seat in Manchester was created. For several years Owens College was the sole constituent college of the University so that here again Manchester has been the pioneer of provincial medical education. It was the first to found a complete medical school and it was the first great commercial city in England to secure, in spite of much opposition and discouragement, the establishment of a great university in its midst. What the future has in store it would be rash to conjecture but it would seem that the plan of a federal university has served its turn and that higher education in Manchester has reached

---

[7] These figures have been calculated from the table given at page 22 of the handsome quarto volume issued in 1900 under the editorship of Mr P J Hartog B.Sc assistant lecturer and demonstrator in chemistry entitled The Owens College Manchester (founded 1851): a Brief History of the College and Description of its Various Departments" (Manchester J E. Cornish) The following extracted from this table and with the percentages added may perhaps be read with interest; the figures for 1900-01 have been added from the last report of the College.

Number of Students at the Owens College

Session	Arts Science and Law Departments.		Medical Department.	Total.	Percentage of medical to total	Percentage of medical to total excluding women department.
	Men.	Women.				
1872-73	337	—	134	471	28·45	28·45
1883-84	400	60*	276	736	37·50	40·80
1892-93	607	93	345	915	36·50	40·50
1899-1900	507	125	370	1002	36·80	42·10

* First year of Women's Department.

a stage when a local university has become not only a necessity but a legitimate claim The change would afford an opportunity for bringing into active coöperation the Owens College and the Royal Infirmary on the one hand and the School of Art, the College of Music, and the Municipal School of Technology, in which you, my Lord Mayor, have taken so much interest, on the other

Thomas Percival

I must now turn back for a moment to speak of a Manchester physician of the eighteenth century who did a great work in his day and generation. The name of Thomas Percival, who was for a short time, soon after its foundation, physician to the infirmary, is probably little known to the present generation, but he was a man who exercised a wide influence in his day and his name deserves to be held in grateful remembrance and reverence for the services which he rendered not only to the profession which he adorned but also to the city of his adoption. Percival "was a Warrington worthy" and a physician remarkable not only for his scientific attainments and benevolent character but also for the breadth of view and width of culture which made him a pioneer in many movements, the effects of which were felt not only in the Manchester district but throughout the whole country The Manchester Literary and Philosophical Society grew out of weekly meetings for conversation held at his house, and his chief co workers in its formal establishment in 1781 were the Rev Dr Barnes, subsequently Professor of Divinity in the Manchester Academy, and Thomas Henry to whom I have already referred. Dr Percival was its first President, an office which he shared with Mr James Massey, one of the founders of the Royal Infirmary, during the lifetime of the latter, and occupied afterwards alone He took an active share in its work, both literary and philosophic, and in several of his scientific papers insisted on the importance of the application of the experimental method to medical inquiries

Dr Percival also took a leading part in a movement which foreshadowed the establishment of technical schools, for he was one of the founders of the College of Arts and Sciences, at which courses of lectures were given on (1) Mathematics and Natural Philosophy (2) Fine Arts, (3) Chemistry with reference to arts and manufactures, and (4) the "Origin, History, and Progress of Arts Manufactures, and Commerce, the commercial laws and regulations of different countries, commutative justice, and other branches of Commercial Ethics" The scheme was not then successful. It came too soon and the country had to wait until towards the end of the nineteenth century for technical schools and until the twentieth for schools and faculties of commerce and economics Percival rendered a very important service to the medical profession and indirectly to the public by his book on "Medical Ethics" The public—if I may judge from remarks which one sometimes hears in conversation and from paragraphs now and then published in the newspapers —look upon medical etiquette as a very mysterious code of rules designed for the benefit of the medical profession and a source of inconvenience to the public Nothing can be further from the truth Hippocrates, the father of medicine, in his Aphorisms, laid down rules for the guidance of the physician in his conduct to his patients, and the relations of practitioners of medicine, surgery, and midwifery to their clients are so intimate, the issues so momentous, involving often all that a man or woman holds most dear—health and life and honour—that it was the duty of the profession to consider very carefully the conduct to be pursued under various circumstances, which in the sundry and manifold changes and chances of this mortal life repeat themselves with a uniformity which would be surprising did we not remember the essential identity of human fate and human emotion in all ages Percival's book on "Medical Ethics"[8] had its origin in a set of rules for the guidance of the staff of the infirmary, and in their preparation he had the assistance of Dr Ferriar and Mr Simmons To these rules Percival afterwards added a series of chapters defining the course which should be pursued by practitioners in private practice towards each other and towards their patients All are designed to ensure that the welfare the sentiments and even the prejudices of the patient should be considered and that no misunderstanding between his medical attendants should prevent them from doing all that medical art permitted for his benefit or from conveying to him or to his friends their considered opinion on his state. Percival had to devote a large space to the conduct which a surgeon should observe when summoned to give his attendance at a duel, but with this exception the book may be read with advantage at the present day and might, indeed, be reprinted with a few additions and omissions as a guide for the present generation His labours to increase the welfare of the people made him a pioneer of sanitary reform and one of the earliest advocates of factory legislation As early as 1775 he communicated to the Royal Society (of which he had been elected a Fellow even before he had taken his degree) a scheme for establishing accurate "bills of mortality," contending that proper registers of population and mortality could alone afford convincing evidence of the effect on health of different occupations and modes of life. He illustrated his subject by comparative statistics showing the influence of overcrowded towns and unventilated workrooms on health. Twenty years later he was a moving spirit in forming the Manchester Board of Health, which sought to prevent disease by inculcating cleanliness, by providing a fever hospital called the "House of Recovery" in connexion with the Royal Infirmary, and by purifying the houses from which the sick had been removed The memorandum which he presented to this board affords striking evidence of his knowledge, foresight, and breadth of view He advocated improved housing of the working classes, the establishment of public baths, the isolation, proper treatment, and nursing of persons suffering from infectious diseases and the cleansing of their clothes and homes, the inspection of mills and factories to ascertain the state of health of the workpeople and their hours of labour, the regulation of noxious trades, systematic cleansing of the streets, and the superintendence of markets where food was sold Angus Smith said truly many years afterwards that "Manchester was then the great centre of sanitary knowledge and Percival the true apostle."

John Ferriar

In his endeavours to improve the sanitary state of the working classes Percival had an able and eloquent helper in Dr John Ferriar Ferriar,[9] like so many others who have won distinction in after life, "was a son of the manse," studied in Edinburgh, where he graduated M D in 1781, and settled in Manchester in 1785 He was a man of considerable literary attainments and learning His "Illustrations of Sterne"[10] traced out—too minutely as some of his admirers thought—the debt which that wayward genius owed to the old French novelists and to Burton's "Anatomy of Melancholy" He wrote an essay on the dramatic works of Massinger,[11] which gained him much reputation, he was himself a poet, among his productions being a didactic poem entitled the "Puppet Show," and a tragedy Soon after joining the Literary and Philosophical Society in 1786 he read to it a paper on Modern Demonology, afterwards expanded into "An Essay towards a Theory of Apparitions,"[12] a slim volume which I would commend to the attention of the Psychical Research Society, for in it he established, to his own satisfaction at least, that a ghost should be regarded "as a symptom of bodily distemper and of little more consequence than the headach (*sic*) and shivering attending a common catarrh" He published also a series of "Medical Histories and Reflections"[13] which show him to have been a careful and accurate student of disease, the best example of his method being perhaps his "Essay on the Medical Properties of the Digitalis Purpurea or Foxglove," in which he shows far more caution and good judgment than the advocates of a new drug usually display It is, however, on his enlightened views as to public health matters that I would rest his claims to remembrance at the present day, and in endeavouring to form a proper estimate of the independence and originality needed to form such opinions at the end of the eighteenth century we must remember that cotton factories and the aggregation of large numbers of workers and their families in towns were then new things and that the infectious doctrine of fevers was far from then holding the assured position which the researches of Pasteur were to give to it in the succeeding century. Ferriar was elected in 1789 a physician to the infirmary to visit home patients, and in the winter of that and the succeeding year an epidemic fever prevailed much in Manchester and Salford. It is not quite clear from his description what this fever was, probably it was typhus, but among the questions which interested Ferriar with regard to it was that of the nature of the conditions prevailing among the poorer classes which he considered should be held responsible for its occurrence. These were the overcrowding especially at night of dirty unventilated "mean lodging houses," often built in blind alleys, the use of cellars for dwellings, the imperfect ventilation of the cotton mills and carelessness in the sale and distribution of old clothes which had been used by the sick. As preventive measures he advocated the ventilation of rooms, the prevention of overcrowding, the licensing and inspection of lodging houses, and the establishment of fever wards to "receive patients from infected houses or from close cellars, or pent-up rooms, where the want of air and the proper attendance leaves little chance of escape to the sufferer."

---

[8] The edition I have used is that published in Manchester in 1803, but the work was republished as late as 1849

[9] The spelling of the name does not appear at that time to have been settled In the dedication of his essay on Digitalis to Major-General Ferrier he spells the name of this gentleman with an "e," while his own appears on the title-page with an 'a'

[10] Illustrations of Sterne with other Essays and Verses Manchester, 1798 second edition Warrington, 1812.

[11] Reprinted by Gifford in his edition of Massinger's works 1805

[12] London 1813

[13] The first volume was published in 1792 the second in 1795 and the third in 1798 A second edition, with additions and omissions was published in London and Warrington in 1810, and a fourth volume in 1813 The whole was also reprinted in Philadelphia in 1816

[Mr. Whitehead here referred to Manchester sanitation, paying a well-deserved tribute to the Manchester and Salford Sanitary Association, and after mentioning the Thirlmere water supply continued as follows:—]

Conclusion.

From a very early date in the history of the British Medical Association the medical profession in and around Manchester has taken a deep interest in its welfare and development. At the first anniversary meeting in 1832 Dr. Charles Henry of Manchester, a grandson of Thomas Henry surnamed "Magnesia," was one of the committee instructed to report on the chemistry of animal fluids as illustrative of pathology; Mr. Thomas Turner was a member of a committee on anatomy, while Dr., afterwards Sir, James Bardsley was appointed corresponding secretary for France.

The British Medical Association was founded in 1831 and in 1835 the fourth anniversary meeting was held in Manchester under the presidency of Dr. Edward Holme, F.R.S., who had long held the office of physician to the Royal Infirmary. This meeting, the first held in Manchester, was memorable in the history of the Association as that at which the system of Branch organisation took origin by the amalgamation with the parent association of the Eastern Provincial Medical and Surgical Association which became the East Anglian Branch. Later in the same year other branches were formed at Wells, Bath, and Southampton and in the following year the Lancashire and Cheshire Branch came into existence at Newton le Willows. Manchester thus saw the first great extension of the local organisation of the British Medical Association and this year it sees another great step towards the perfecting of that organisation. Burke called representation "the cure for all evils in the colonies." May it have a similar influence in our Association. The serious business of securing the right kind of representation will be the only difficulty you will have to contend with. I trust that the results will be to make the Association stronger, larger, and more influential than ever. The Association held its annual meeting again in Manchester in 1854 when Mr. William Wilson, surgeon to the Royal Infirmary and well known for his important contributions to obstetrics and gynæcology, presided. The membership had grown to over 2000 and an important proposal making a further stage in the development of the Association was made. This was that the title should be changed from the Provincial Medical and Surgical Association, which it had hitherto borne, to that of the British Medical and Surgical Association. This change of name betokened an extension of the Association's work to embrace all British practitioners of medicine. Finally, after a good deal of discussion, the familiar title of the British Medical Association was chosen and formally adopted in 1856. Under that name it has grown and flourished and it will, I hope and believe, continue to flourish, serving as a connecting link between the members of our scattered profession—scattered in their student days in many schools, obtaining their diplomas and degrees from many universities and corporations, and ultimately practising in every district of the United Kingdom and every region of a united empire.

It now only remains for me to thank you for the attention with which you have been good enough to listen to me. Much of what I have said was, perhaps, known to many residents in the district. My object has been to act the part of a chamberlain who in the old royal courts was the introducer of ambassadors, for you, gentlemen, who have honoured us by visiting Manchester, coming as you do, from foreign countries, from the many distant parts of the British empire, and from every district of the United Kingdom are the ambassadors of the profession of medicine. May your labours during the next few days help to draw closer the bonds which unite the various departments of our art, which in every clime has but one aim—the prevention or the alleviation of human suffering.

In conclusion, let me quote to you the words which, though written three centuries ago, yet express so aptly the sentiments which should animate a congress such as this. The noble words of the great Lord Bacon in his preface to the "Elements of the Common Laws of England," might, I think, be taken as the motto of our Association. "I hold every man," he says, "a debtor to his profession; from the which as men, of course, do seek to receive countenance and profit, so ought they of duty to endeavour themselves by way of amends, to be a help and ornament thereunto. This is performed in some degree, by the honest and liberal practice of a profession, when men shall carry a respect not to descend into any course that is corrupt and unworthy thereof, and preserve themselves free from the abuses wherewith the same profession is noted to be infected; but much more is this performed if a man be able to visit and strengthen the roots and foundation of the science itself, thereby not only gracing it in reputation and dignity, but also amplifying it in profession and substance."

Address in Medicine

THE STUDY OF THE NATURAL HISTORY OF DISEASE THE BASIS OF ALL ADVANCE IN ITS TREATMENT

Delivered at the Annual Meeting of the British Medical Association at Manchester, July-August, 1902,

BY SIR THOMAS BARLOW, BART., K.C.V.O., M.D., F.R.C.P. LOND.,

PHYSICIAN TO HIS MAJESTY'S HOUSEHOLD; PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—Twenty-five years ago the British Medical Association met in this city and the Address in Medicine was given by one who fitly represented the Manchester School and whose name is illustrious amongst the leaders of our profession in the Victorian epoch. William Roberts had many remarkable gifts, but the combination in his mental equipment of infinite painstaking in homely detail and of philosophical insight and foresight gave alike to his public utterances and to his conversation a suggestiveness and charm which can never be forgotten. The address which he gave within these walls was a notable example of this. It was a masterly discourse on the acute specific diseases in their relation to contagium vivum which subsequent research has left intact and which in many ways was prophetic as to future developments. *Nihil quod tetigit non ornavit.* The recollection of his discourse gives humbling reflections to one who has to take up the parable where Roberts left it. In the address which you have asked me to give it would be impossible even to enumerate all the advances which medicine has made during the quarter of a century which has elapsed since we last met in this hospitable city.

EMPIRICISM AND SCIENCE IN THERAPEUTICS.

We live in worrying times and we have often to possess our souls in patience. There are those who still maintain that medicine has no claim to the title of an exact science, and yet some of the most estimable of our fellow citizens do all that lies in their power to hinder the employment of one of the methods which contribute towards making medicine an exact science. On the other hand, in view of the striking development of some of the modern applications of the physical forces, there are not wanting those who sneer at us as bigots and obscurantists when we hesitate to write a blank cheque for the reckless employment of those modern applications in diseases of which our knowledge is very limited.

But let us reflect how strange and varied has been the progress of practical medicine, by which I mean all that body of knowledge concerned with the cure and the prevention of disease The history of the earliest efforts in the relief of pain is wrapped in mystery Perhaps they were not unlike the sports or spontaneous variations which are claimed by the Darwinian hypothesis as the first steps in the development of species, those variations which were useful to the organism being perpetuated by a survival of the fittest But at all events—and let us frankly admit it—the basis of our practice is empiricism, and the basis of all our practical life is empiricism But there is good empiricism and bad. The good empiricism continually strives to follow Nature's lead and shed that which is foolish and useless while preserving that which is essential And good empiricism, by carefully recording cases, noting the results of changes made first by chance and then by design, may at length assimilate to a truly inductive process, even though there are many unknown quantities But as Nature herself seems sometimes to fail, and leaves behind vestiges and survivals in our bodily conformation which may give rise to trouble, so we also in our treatment sometimes preserve methods of long past utility which may now and again be harmful. How much we owe to the good sceptics—or, in other words, the independent observers—of whom Sydenham was one, and of whom, in our generation, there was no finer example than Sir William Gull These are the men who have taught us to look disease straight in the face with our own eyes and to realise what is its natural cycle, and ask ourselves within what limits we can reasonably hope to modify it. And as a warning against becoming self centred and self opinionated let us never forget Bacon's wise aphorism "For as they were men of the best composition in the State of Rome which either, being Consuls, inclined to the people, or being Tribunes, inclined to the Senate, so, in the matter we now handle, they be the best physicians which, being learned, incline to the traditions of experience, or, being empirics, incline to the methods of learning" It is in the period of half knowledge that the practice of medicine has often cut a sorry figure For theoretical lines of treatment, based on incomplete physiological and chemical data, have often produced melancholy failures. But the outcome of the new experimental pathology of the last quarter of a century, controlled by clinical observation, applied and tested by clinical experience, has justified us in claiming that at length our work has ceased to be fairly described as groping in the dark and that in some definite instances medicine has justified for itself the designation of an exact science

In drawing attention to some recent notable advances in the healing art I will ask your consideration and support for this thesis the advances in the treatment of disease have been real and satisfactory in proportion as they have been harmonious with the complete knowledge of the natural history of disease I do not say that good treatment owes its origin entirely to pathology—far from that, it has often ante-dated pathology—but in proportion as pathology has become complete it has rationalised good treatment and refined it, separating, so to speak, the ephemeral from the permanent, the accidental from the essential, as well as the harmful from the beneficent. Moreover, in these last days in not a few instances the true pathology has laid down new therapeutic lines which have been justified by experience.

BACTERIOLOGY AND TREATMENT OF DIPHTHERIA

Let me choose as my first illustration one of that group of acute specific diseases to which in his discourse Sir William Roberts gave his chief attention I will ask you, as practical men, whether there is any disease within your knowledge in which bacteriological investigation has made so profound a change in our attitude as to the malady and its treatment as it has in diphtheria? Recall, I pray you, the chaotic and bewildering state of doctrine on this disease only a dozen years ago There were the endless, and not altogether academic, disputes as to the difference between croup and diphtheria, as to whether there was a true membranous croup which was different from laryngeal diphtheria, and as to the diagnostic differential signs of diphtheria which appeared to elude the most careful anatomical definition Malignant diphtheria of the throat was easy to diagnose, but as to the nomenclature of mild cases simulating follicular tonsillitis and of the throat exudations complicating scarlet fever an experienced man was the last person to dogmatise It was only at length by studying cases in epidemic groups and especially by noting the paralytic sequelæ that we learned how widely we had to cast our net in order to include examples in which there had been no visible membrane at all though there might in some of them have been exudation in the post-nasal region and, for a time, thin irritating discharge from the nostrils And how exceedingly diverse were our opinions as to its etiology We were never prepared to deny that exposure to cold was a cause and after cold came drains Drain-poisoning, serious as it is in lowering vital resistance and preparing a suitable soil, has been often made to bear more than its fair share in the immediate causation of specific disease, and diphtheria was a notable case in point. Sir William Jenner, whose enlightened doubts were nearly as valuable as his absolute statements, would never admit that the direct relationship of diphtheria and drain emanations was proved. But the confident assurance of many people on this doubtful point was often exceedingly mischievous, for though it led to sanitary investigations and helped sometimes to bring about sanitary improvements it also led to the quiet ignoring of other possible sources of the disease. There was a time, not many years ago, when cases of membranous croup were treated in children's hospitals in ordinary wards, and there were those who stoutly maintained that these cases were not contagious The further study of epidemics led to the conclusive proof that in some cases the disease was disseminated by milk. Then came the observation that epidemics were often followed by sporadic cases, or preceded for a time by mild and ambiguous sore throats Country villages and isolated homes gave their quota as well as crowded streets. By degrees, even in apparently sporadic cases we came to attribute more and more importance to insidious personal contagion, and to see that the disease was maintained and transmitted by the moving to and fro of slight cases, especially in schools and places where children were closely aggregated Increase of the disease seemed to correspond with the period when compulsory school attendance was enforced, and there grew up a strong presumption in favour of the tenacity of infective material associated with bedding and clothing

And if there were wide differences of opinion as to the signs and causation of the disease, how varied were the different lines of treatment! One recalls the routine administration of antimonials and emetics in laryngeal cases which held sway so long, probably on account of the confusion in diagnosis The cases that were benefited were those of simple laryngeal and tracheal catarrh with spasm, but the true membranous cases were almost certainly made worse It was but slowly that the consensus of opinion grew in favour of quinine and iron and other tonic methods The local applications were multiform, and who does not remember the pitiful struggles of many a tender child at the swabbings which were fruitlessly and repeatedly applied? Many of the stronger local applications were actually mischievous The continuous steam kettle and the tent and the irritating and headache producing antiseptic inhalations come back to us and make us realise how often we lowered the constitutional vigour of the patient while we vainly attacked the local disease. The fear of cold air in the treatment of laryngeal affections was also maintained in respect to faucial diphtheria and a room temperature over 70° F day and night, moist like a tropical hot-house, was so constant that it required some hardihood to break through these cast-iron conventions When the bacillus of diphtheria had been isolated by Klebs and the inoculation of it in animals had been demonstrated by Löffler to produce diphtheritic lesions the first step had been taken in unravelling the skein. Let us consider how these discoveries, followed by those of Klein, Roux, Sidney Martin, and others, illustrated and explained the puzzling clinical facts First, the polymorphism of the bacillus is very suggestive The long and short varieties, it has been shown, may occur as pure cultures or side by side, or in successive cultures apparently one form may be replaced by the other Though these varieties cannot as yet be correlated to different types of membrane, yet their discovery prepares us for considerable variation in gross naked eye characters Secondly, the variation in virulence of the bacilli going down to an actual vanishing point with little morphological alteration has its transcript in clinical experience. When in an ordinary case of faucial diphtheria the nose becomes affected and a thin ichorous discharge appears at the nostrils the gravity of the case is always increased On the other hand there are cases of children attacked with thin fibrinous exudation obstructing the nostrils in which the Klebs Loffler bacillus has been identified and yet there is little constitutional disturbance and apparently very slight infectivity There is a form of chronic diphtheritic ophthalmia with thick exudation which presents many similar features. Thirdly the detection of the diphtheria bacillus in the secretions of the throat in cases at first clinically indistinguishable from follicular tonsillitis gives the clue to the puzzling cases which the study of epidemic groups had brought home to us—namely that paralytic sequelæ can occur when most careful observation has failed to identify any antecedent visible membrane. The persistence, sometimes for months, of the bacillus in the fauces of those who have passed through an attack of diphtheria when all membrane has long since disappeared gives us the clue to the occasional prolonged infectiousness *of those who have had this disease, and seems to enforce* the need of special arrangements for diphtheria convalescents. It is the experience of those interested in day school epidemics that a slight nasal discharge associated with imperfect resolution of the lymphatic glands are the clinical danger signals to be looked for and which suggest the bacteriological investigation for continued sources of dissemination.

The detection of the diphtheria bacillus without exudation in the fauces of medical men and nurses attending cases of this disease is one of those valuable and suggestive facts which emphasise the importance of keeping the mouth and throat clean and of maintaining the vital resistance of the attendants by good food regular sleep, and plenty of fresh air In the old days how often the risks of the diphtheria nurse contracting the disease have been increased by the close, stuffy sick room the long uninterrupted hours of attendance, and the inadequate meals Moreover the tenacity of the bacillus and the fact that cultures can be made from membrane that has been in contact with a textile fabric even after some months, accentuates the importance of destroying as much as possible in the way of contaminated clothes and of not being content with perfunctory disinfection But we are further indebted to the bacteriologists for solving some of our clinical difficulties by demonstrating that not all false membranes are diphtherial. The streptococci, for example, seem capable of giving rise to pseudomembranous deposit The exudation occasionally present in early scarlatinal throats, which are extremely red and swollen is not generally true diphtheria, and this harmonises with what is found clinically that the exudation seldom spreads, and that paralysis does not supervene. On the other hand the secondary membranous exudations which sometimes supervene in measles and in the late stage of typhoid fever appear often to be due to true diphtheria bacilli. But further investigation seems to be required as to the virulence of and the dissemination from the secondary cases. Thus far as to the bacilli. But the skein becomes still further unravelled by the discoveries of Roux Yersin and Sidney Martin on the toxin of diphtheria. The first two observers separated the toxin from the bacilli and produced by inoculation many of the symptoms of the disease but *misses* the formation of false membrane

Whether as Sidney Martin maintains, the bacilli at the local site of the disease elaborate a ferment-like body which, subsequently affecting the tissues, digests them and the products of this digestion constitute the toxins or whether as others hold the bacilli themselves elaborate the toxins, is not material The solid gain to knowledge is that for the most part the mischief is elaborated locally at the site of the diphtheritic membrane and not to any great extent by multiplication of the bacilli themselves in the blood and other tissues. And this leads us to see the justification of the researches of Behring and his fellow workers which eventuated in the practical application of the methods of immunisation and the preparation of an antitoxin. It is beyond my purpose and outside my province to go into the complicated questions of the preparation and standardisation of diphtheria antitoxin But surely it is right in this meeting of practitioners who have to deal with disease to insist on the revolution which this treatment has made. The statistics are striking enough, for they show a reduction of mortality between one-third and one-half But statistics are not the only test upon which a medical man bases his practice. The manifest alteration after the use of antitoxin, even in a most unfavourable and ultimately fatal case, is convincing enough to an informed person that we have here a fundamental remedy of enormous potency When, within 48 hours, we see a young subject with malignant diphtheria accompanied by secondary infections which are on the verge of setting up septicæmia so far relieved after the use of the remedy that the glands are reduced in size, the cellular tumefaction of the neck is lessened, the membranous exudation is arrested and begins to separate at the edges the tongue is more moist, and the general state ameliorated, we know that something has been done to control the disease processes with which no previous treatment with which we were acquainted was in the least degree comparable. Furthermore, in cases in which tracheotomy has to be performed not only are the mortality statistics improved but we see for ourselves that the membrane formation ceases to spread and the tube which has formidable disadvantages of its own can be withdrawn much sooner and the risks of ulceration and *stenosis can be thereby lessened. Moreover those of us who* were doubtful about the expediency of intubation in this disease on account of the difficulty of providing for the evacuation of the membrane below the tube are now only too glad to admit of its applicability because of the gradual melting away of the membrane.

Since the introduction of the antitoxin the urgency of local applications to the fauces has become lessened to a marked extent. We are told that antitoxin only neutralises the toxin but does not destroy the bacilli themselves A weak mercurial solution which attacks the bacilli, though it coagulates the albumin, and an alkaline solution which favours the solution of the membrane, seem to be all that are needed. By too much zeal in local applications we interfere with the protective action of the phagocytes and the old corrosive applications are entirely ruled out. With continued experience the limitations of antitoxin are becoming more and more clearly understood. A careful man seeks the assistance of the bacteriologist in every doubtful case but does not wait for his report for he knows that the certainty of success depends on the remedy being introduced early say within the first three days, and that the risks of its employment are insignificant. The existence of secondary infections makes him far more anxious and he feels compelled to warn the friends on that account, but it does not prevent his applying the diphtheria antitoxin even in very grave cases Experience does not seem to support the concurrent use of anti streptococcic serum. As to the rashes the pyrexia, and the joint pains which appear up to the second week after the injection, they seldom give rise to anxiety when we are prepared for them and recognise their nature nor do they require special treatment We know now that they really depend on the serum *per se* and not on the special antitoxin. As might be expected there are occasionally inflammatory incidents from imperfect aseptic precautions in the injections and such incidents ought not to occur but let us remember that there are also like risks which occasionally arise with hypodermic injection of morphine and other remedies and those we accept.

Some of the earlier objections as to the effects of antitoxin seem to have been made by those who were inadequately familiar with the symptoms of diphtheria itself Everybody knows that albuminuria is common in diphtheria and that suppression of urine is not rare and there is no reason to believe that antitoxin has any effect at all in producing them. May I here in speaking of suppression of urine by way of parenthesis refer to a practical point in nursing—namely the extreme difficulty in inducing nurses to give abundant plain water to patients suffering from diphtheria and other febrile illnesses generally and also to the importance of aiding renal secretion and quenching thirst when there is distressing vomiting by giving weak saline rectal injection ? As to the incidence of diphtherial paralysis in cases treated by antitoxin it seems reasonable to suppose that many of those who develop paralysis after antitoxin would otherwise have died before there was any chance for the paralysis to become manifest. Goodall has shown, however that there are no more fatal cases of paralysis in those treated by antitoxin than in those not so treated. It seems probable from Martin's researches that the diphtheria toxin begins to affect the nervous system very much earlier than would be supposed from the obvious clinical manifestations and possibly when once initiated, the neuritic changes go on in spite of antitoxin, just as in some other forms of peripheral neuritis they persist and go through their own evolution after the removal of the cause.' Of the prophylactic value of the diphtheria antitoxin for those in a family or institution where there is a case of diphtheria we can only say that there seems now a large body of experience in support of its efficacy, although the period of immunity conferred does not exceed three weeks.

TETANUS

While the diphtheria antitoxin treatment is in every way the most satisfactory of all the serum methods, the other members of this group of therapeutic measures are full of suggestion, and it is worth while briefly to consider a few of them. Thus, with regard to the tetanus antitoxin, although the experiments on immunisation of animals have not furnished us with a successful method of dealing with the severe and acute cases of human tetanus, yet some benefit has been gained in the chronic forms It is interesting to observe that the tenacity of the combination between the toxin and the nervous tissues which was shadowed forth in diphtheria is in tetanus the dominant factor It would appear to be the tissues of the central nervous system for which the toxin has a special affinity, and the later investigations point to the necessity of subdural injections into the cerebral substance itself, as well as into the cellular tissue, and to the employment of far larger doses of the antitoxin than the first immunisation experiments suggested.

OTHER EXAMPLES OF SPECIFIC REMEDIES

In the other examples of this kind of treatment we have to depend on very incomplete data. For example, in rabies we are still ignorant as to the micro-organism which, we are none the less convinced, is the cause of the disease But the knowledge that the poison is lodged in the cerebro-spinal tissues has led, in the hands of Pasteur and his pupils, to the most fruitful results The working hypothesis that in the dried spinal cord of an animal that has died from rabies the micro organisms are destroyed, but that the immunising substances remain active, seems to have been justified by experiments based upon it and by its applications There surely can be no doubt of the prophylactic value of Pasteur's methods so far as those who have been bitten by rabid animals are concerned, although no beneficial effects follow their employment in the developed disease But when a complete analysis of the life history of the organism has been attained we may fairly look for still greater results in the therapeutics of this disease Is it unreasonable to suggest the same thing with respect to the great triumph of English protective medicine—namely, vaccination? One of the best results of the recent Royal Commission was that it gave the *coup de grâce* to the easy optimism of those of us who considered that there was finality in what had been already accomplished and that nothing more was needed than to continue on the old lines But the most recent methods of preparation with the carefully regulated glycerination and the getting rid of so much of the secondary infection, for which we are indebted to Copeman, mark an enormous advance in the practical application of vaccination Who can doubt that there are still further triumphs in store for us when the organism has been discovered and its natural history has been completely worked out? Of plague, cholera, and typhoid fever I will not speak for the inoculation methods are still *sub judice* With respect to the employment of anti streptococcic serum we are met by the most various testimony Some cases of erysipelas and puerperal fever and some of those most desperate cases of acute septic mischief, following on infections from necropsies, have been strikingly benefited by the use of injections of this serum Some cases of infective endocarditis appear to have improved, but a great many others have shown no response whatever It would appear that although streptococcus is the organism common to many forms of septicæmia and although morphologically no differences can be established according to the lesion from which it is derived, yet that there must be many different strains, and that the serum of an animal that has been immunised from one strain will not necessarily prove beneficial to an animal subject of another strain. Meanwhile it would seem that in any case of formidable septicæmia, when there is substantial reason to doubt whether the patient can cope with it successfully, we are not justified in withholding the use of anti streptococcic serum, which should be recently prepared This is pre eminently one of the subjects in which we may look for notable advances from fuller knowledge of the natural history of these organisms

THE TREATMENT OF TUBERCULOSIS IN THE LIGHT OF MODERN DISCOVERIES

Koch's great discovery of the tubercle bacillus in 1882 has been so far reaching and comprehensive that the simplification which it has brought about in our knowledge and in the mode of grouping of a great body of facts seems almost incredible. The most important outcome was that it confirmed the doctrine that tubercle should be placed amongst the chronic infections and so helped us to realise, in some sense, the kind of enemy with which we had to deal. With respect to the tuberculin treatment of tuberculosis it cannot be denied that the results obtained have been on the whole unsatisfactory and tentative And when we consider that under the most favourable circumstances both forms of tuberculin can only claim to set up fresh activity in the neighbourhood of pre existing tuberculous lesions, with which fresh activity the reaction temperature is associated, it is clear that the result must be, to say the least, problematical With localised subacute and indolent lesions such as we get in lupus we might fairly expect that such increased activity might sometimes be followed by improvement and that has unquestionably been observed also in some cases of tuberculosis of joints But with respect to visceral lesions there is always some risk of dissemination following this renewal of activity and of the setting up new inflammatory action and necrosis instead of fibrosis in the lesions themselves

The importance of the tuberculin injection as a test for the tuberculous lesions in cattle seems to be very great indeed, but the justifiability of the employment of this test in the human subject for the determination of a doubtful lesion is, I think, open to question although it has been extensively employed without proof of harmful effect The most important pathological fact bearing on the therapeutics of tubercle is the enormous frequency of unsuspected tubercle as proved by investigation after death of persons dying from other causes than tubercle Thus, necropsies on people dying from surgical injury and every form of acute and chronic disease show in a great many cases one or more old tuberculous lesions And the younger the subject the more frequently are tuberculous lesions found Thus, from the careful synopses published by several skilled pathologists, it would appear that about one third of the children under two years of age who die from all causes in the children's hospitals show tuberculous lesions The first reflection that forces itself upon us is the enormous frequency of unsuspected tuberculous illnesses that occur in the population around us, the second and equally important reflection is that there exists a tendency in the human subject to spontaneous limitation and arrest, and the third reflection is that there is an extreme frequency of local limited tuberculous deposit as compared with the generalised disease. How, then, if tubercle has gained admission are we to aid Nature in this spontaneous tendency to limitation and arrest?

Let us by no means deny the possible utility of fresh attempts at serum therapeutics nor the tentative use of disinfectants introduced into the blood stream, such as the formaldehyde plan of Dr R, Maguire These methods may prove beneficial in the concomitant and secondary infections even if they do not control the tuberculous process pure and simple. Also we are grateful for all that the surgeons have done in respect to glands and joints and abdominal tuberculosis and for the recent applications of Roentgen rays and Finsen's method to cutaneous tuberculous lesions Bu surely the teaching of pathology is that the fortifying o the general resistance of the individual is the most important indication of all Real, true advance always tends t simplification, and the great fundamental therapeuti remedies are the employment of fresh air and sunshine, o good food, and of regulated exercises This, surely, is th inwardness of what has been called the sanatorium treatment Let us gratefully recognise what Brehmer and Dettweile and Trudean and Walther have taught us, but in th meeting of the British Medical Association it is fitting tha we should remember that 60 years ago an Englishman— village general practitioner, George Bodington of Sutto Coldfield—taught, both by precept and by the results o actual experience, what were the proper methods of treatin phthisis The measures upon which he relied were that th patient should live most of the day in the cool open air, tha his rooms should be thoroughly ventilated and in temper ture not vary greatly from that of the outer air; that dail driving or riding and as soon as possible walking should be enjoined, that a generous diet should be given, and that all this should be carried out under the assiduous daily and even hourly supervision of a practitioner living under the same roof or close by Bodington's criticisms of the orthodox antiphlogistic doctrines of his time were as sensible as they were trenchant, but it may be questioned whether in his rebound from them he did not attribute undue value to sedatives and stimulants as adjuncts to his treatment But the main lines which he laid down are admirable.

Let us now consider in detail what we have learned from recent sanatorium experience in our own time. First, we have learned the value of hyperaeration and of establishing tolerance to cold and to exposure to variations of temperature. The value of hyperaeration is not summed up in its affording more effective oxygenation to the lungs, parts of which are *hors de combat* though that counts for a great deal. The access of free air is also a natural and wholesome stimulus to the nervous system. It increases the appetite and lessens the languor and exhaustion of a chronic febrile disease which the still warm air of the old sick room did nothing to relieve The getting rid of the liability to catarrhs of the upper passages by free exposure to pure fresh air had been known to us apart from phthisis if we had only had the sense to apply it, and the enormous difference between sitting in the open and sitting in a draught was an old story which we ought to have remembered. The daily exposure to free, cool air has also been shown to have a direct benefit in lessening pyrexia diminishing sweating and improving sleep. And can we exaggerate the value of the immeasurably greater intake of direct sunshine which this treatment ensures as compared with any ordinary mode of life? With regard to the employment of exercise, the time when it is taken, and the exact amount of it, the sanatorium experience has shown us that the most important therapeutic indications depend on the careful record of temperature. With regard to food we find that the exaggerated fastidiousness which is so hard to deal with in phthisis is less of a difficulty under sanatorium treatment than under ordinary conditions, that the number of patients who are unable to assimilate milk is exceedingly small and, finally that the enforcement of large mixed meals at any rate for a period, is on the whole justified by the results of chemical investigation and of the actual well being of the patients. But, further there is the educational side of the sanatorium. The patient is instructed as to the importance of the disposal of sputa and as to the methods by which a phthisical patient may live with his fellow-creatures without risk to them. Surely the imperative necessity of enlightened and unremitting medical supervision in work of this kind is self evident. Whether there will be evolved any better method of carrying out these indications for the treatment of phthisis in its early and middle stages remains to be seen So far as the rich and well to-do are concerned it will probably be found that the sanatorium fulfils the role of a school which shall educate them in methods which can subsequently be carried out efficiently at home if the conditions are favourable. But with respect to the poor it is only now and then that the home conditions, *even* in the country admit of adequate early treatment and for them in the immediate future we have to look forward to the multiplication of sanatoriums

It seems desirable that we should speak more guardedly about the *cure* of consumption and insist rather upon its *arrest* In that way we throw upon the individual as well as upon the enlightened community the vital necessity of a prolonged after-care of the tuberculous subject. This is another of the instances in which bacteriology has given scientific emphasis and direction to rational therapeutics, for we remember how *many of our patients, in spite of having* increased greatly in weight and general nutrition and of having improved enormously in physical signs nevertheless continue after their sanatorium course to expectorate once a day sputum containing some tubercle bacilli. But even when the general nutrition leaves little to be desired when, so far as physical signs are concerned, the lungs are dry when the temperature is normal after exertion and at every part of the day is it wise to adopt the optimist tone and to assure the patient that he is as sound a man as ever? We cannot, even in the most promising cases exclude the possibility of the reawakening of activity around old foci nor of entirely new local infections and we must continually hark back upon the old text of maintaining the resistance at its maximum. Meanwhile for the poor man there is the question of bread winning and there is the danger of relapse when he returns to unhealthy surroundings.

The question must be faced whether systematised arrangements can be made for open-air occupation. Whether this can best be done in colonies, like the epileptic colonies where horticulture is taught, or by some method comparable to boarding out, requires much consideration. It is also clear that to meet the full needs of the poor there ought to be some form of special hospital provision made for incurable and rapidly advancing cases of phthisis These are certainly not suitable for the sanatorium and it is unfair to frustrate the true work of the sanatorium by sending such patients thither On the other hand, with our present arrangements of general hospital and infirmary wards the contiguity of cases of acute and curable disease with those of advanced phthisis in which there is copious expectoration is always an anxious matter even when precautions are taken We may, nevertheless be grateful to the bacteriologists for enabling us to give the confident assurance to many a poor consumptive that it is the dried sputum and not the moist material which is the most important and if the devoted wife who is nursing a consumptive husband will only carry out scientific cleanliness if she will strive for the greatest amount of ventilation possible and if she will do her best to maintain her own personal resistance at a maximum her risk becomes almost a negligible one.

Looking still further ahead, it is clear that the community is beginning to realise the necessity of going to the root of the matter and of seriously attempting to prevent consumption as well as to cure it. First as to the prevention of infection, voluntary notification has been established in Manchester and elsewhere with very good advantage. There seems to be very little difficulty in securing disinfection of rooms after a fatal case has occurred in the abodes of the poor and experience would seem to show that with tact the notification of phthisis during life may be followed by sanitary inspection and by much useful guidance as to ventilation, cleanliness and disposal of sputum. The example of some of the Latin races has been often quoted to us in respect to the popular estimate as to the infectiousness of phthisis, but Heaven forbid that our people should in consequence of any such teaching become prudential cowards and treat the poor consumptive as a leper and a pariah There have been undoubted cases of hardship in the way of summary dismissal of young people from places of business on account of cough and the suspicion of phthisis It ought to be an honourable understanding that no employer should dismiss such a person without using his best endeavours to secure admission for him or her to a sanatorium or to some adequate equivalent of the sanatorium.

Passing from the care of the individual sufferer and the protection of his immediate neighbours to the wider claims of the community let us do our utmost to secure in our towns the greater access of sunshine and not only strive for large open spaces but for free space round our dwellings. Let us face the question of free air in our houses and work shops and schools and all public buildings and wage unceasing warfare against the lodgment of dust in theatres and all public buildings and insist on the importance of moist cleansing as distinguished from mere sweeping of dusty material There must come many changes in our modes of home life in large towns, in our house architecture and lighting warming and furnishing Surely these are not altogether utopian and foolish forecasts to keep before us and when substantial progress has been made and the public conscience has been quickened and enlightened the sanatorium may be regarded as a temporary and provisional arrangement only and more may be done in the way of rational home treatment even at its outset. At any rate, it is certain that there will be less of it to treat.

With regard to the relation of human tuberculosis to that of the lower animals Koch's remarkable deliverance has no doubt led to much searching of heart, but we must possess our souls in patience and wait for the results of further and more exhaustive investigation. Meanwhile, let us do all we can to prevent the relaxation of the hard-earned sanitary regulations which have been obtained for the protection of the community in respect to cattle There can be no doubt of the wrong done by allowing milk to be supplied from a cow with a tuberculous udder and the value of the tuberculin test for revealing this disease has been definitely proved. The instruction to our patients to scald their milk should be given universally, although we may condemn the prolonged and repeated sterilisation at high temperatures which has lately become fashionable But I must confess that for my own part I have not yet been convinced that the abdominal tuberculosis of young children is in any large amount the result of infection pure and simple from tuberculous milk. Human tuberculosis absolutely limited to the alimentary canal and to the mesenteric glands is not a very common disease. I believe that for young as well as old the entrance of tubercle is in far greater proportion by the respiratory tract and that its resting place is in the bronchial glands and the lung alveoli, and that in a large number of cases the infection of the mesenteric glands is a secondary one or part of the general infection. Also, the habit of swallowing the sputum, which is so constant in children, ought to be taken into account in the consideration of the production of intestinal and mesenteric tubercle Three colleagues of mine at the Children's Hospital, Great Ormond street, London, W C, who had held the post of pathologist there—namely, Dr W S Colman, Dr F E Batten, and Dr G F Still—have published the results of their investigations, and these all point in the same direction.

The carefully recorded observations of Dr J W Carr, Dr L G Guthrie, and Dr Northrupp likewise show the great preponderance of bronchial glands as the common site of tuberculous lesions in children The most important antecedent and predisposing conditions for tuberculosis amongst the children of the poor are measles and whooping cough and the close, stuffy rooms in which they are treated and in which their convalescence takes place. The response of children to open air treatment is if anything more striking than that of adults, and I believe that it will be found that they are more tolerant of exposure to wind than adults are. The importance to healthy children of passing a great part of the day in the open air has been gradually apprehended by the rich, and the poor have been compelled to learn it by their home conditions, but neither rich nor poor have as yet appreciated how large a slice of every 24 hours of a child's life is passed in the bedroom. The traditional fear of night air and of wide open windows, which is perhaps the survival of ancient malarial experience, has still to be unlearned in this country Moreover, we should never forget in our large manufacturing towns the importance in children of paying regard to the unhealthy mouth cavity, which is due to bad teeth and inflamed gums, and likewise to morbid conditions of tonsils and naso-pharynx which make open pathways for the admission of tubercle and lead to localised and limited infections of the glands of the neck Surgery has done a great deal to help us in dealing with advanced lesions, but surely cleanliness of the mouth in the large and complete sense, improved ventilation, the early instruction in nose breathing and timely change to hills or seaside after acute specific illnesses and chronic catarrh ought to anticipate and prevent surgical interference in a large number of cases

Clinical observations ought in future certainly to be carefully made as to the relation of tuberculous milk to the infection of the glands of the neck, but it is exceedingly difficult to get conclusive evidence. What is the practical bearing of the later investigations with regard to the bearing of heredity on tubercle? We have here a conspicuous example of the fact that the more complete our knowledge of the natural history of a disease the more clearly we realise that observations which at an earlier period seemed absolutely conclusive in one direction become susceptible of other interpretations As we know tubercle now we must admit that if there were definite inheritance of tubercle it would imply a direct transmission of a tangible material from parent to child which would be capable of subsequent dissemination Now, to say that it is impossible that tuberculous material should exist in the new born child would, no doubt, be an ultra dogmatic and unjustifiable statement. So far as I know there is no evidence of any case of fœtal tubercle in the human subject, but there is evidence that the calf may be affected with fœtal tubercle, though this is infinitely rare It is certainly significant that in infants under 12 months old tubercle is not very common, as we should expect it to be if congenital tubercle occurred. It is in the second year that tubercle becomes very common indeed. The successive attack of several members of a family by tubercle, instead of pointing necessarily to an inheritance of the disease, is often explicable by their being subjected to the same or similar infective conditions Is there, then, no inherited tendency to develop tubercle at various periods of stress—what has been called inherited vulnerability? That we cannot deny—though it is impossible to prove—but strictly this amounts to nothing more than saying that a given child is delicate and unstable, and all delicacy, whether the parents be tuberculous or not, means weakened resistance to the inroads of disease This is not an academic question, it is a practical one Sensible moralists wi remind us that the doctrine of original sin is responsible f the excuse and wholesale condoning of much wrong doin In our domain we know how often the abject acceptance the doctrine of heredity has taken away the courage an initiative alike of practitioners and of responsible relativ in dealing with delicacy of constitution as well as with pr nounced tuberculous disease

THE PRACTICAL RESULTS OF THE SCIENTIFIC STUDY O MALARIA

In the whole range of medicine there is scarcely a disea which illustrates our opening thesis more forcibly than do malaria. The story of the investigations of our countryme Manson and Ross, are fresh within our memory Up to certain point the life history of the malarial parasite ha been made clear by the observations of Laveran an Marchiafava. The amœba like bodies enter the red co puscles, live on the hæmoglobin, and divide into spore The latter burst through the envelope of the corpuscl become disseminated in the blood serum, and repeat th process of the parent organism. But other forms do n develop spores and in some species these assume with the corpuscles a crescent like shape When the crescen like bodies are observed for some minutes on the war stage a change of shape takes place and motile filamen are observed to escape from them. It was at this poi that Manson's insight led him to join issue with the Itali observers, who looked on this stage as one of degeneratio whilst Manson claimed that it suggested another li cycle of the organism within the body of some host oth than man, which host should be the means of commun cating the parasite to man. That intermediate host, h reasoned, must be a suctorial insect, and predicted that would prove to be the mosquito Ross's investigatio established the truth of this hypothesis beyond any ca and narrowed down the number of possible hosts to gnats the genus anopheles The next inquiry was to ascertain th important facts as to the habitats of the anopheles and i mode of life. And Ross, in the expedition sent out by th Liverpool School of Tropical Diseases, was able to show th the larvæ of these gnats were to be found in shallow poo which were not big enough or permanent enough for fis and yet were not small enough to dry up between showe The drainage or filling up of these pools in the neighbou hood of human habitations, or systematic destruction of th larvæ by the application of paraffin, appeared to be th readiest way of dealing practically with the problem

The further verification of the mosquito theory was final set forth by the results of an expedition planned und Manson's direction, and carried out by Dr L W Sambon an Dr Low of the London School of Tropical Medicine Th objects of this investigation were two-fold (1) to arran for the transmission to London, with proper precautions, specimens of anopheles which had been infected wi malaria, and to arrange for a healthy person to be bitten them, and to watch the result as to the induction of malari fever, and (2) to instal two healthy persons in a malari district through the whole of a fever season, provided the with efficient protection against mosquito bites, and to no the result Ostia, in the Roman Campagna, was chosen f the erection of the experimental hut, which was construct with the greatest care and furnished with wire netting as to be absolutely mosquito proof No quinine or oth prophylactic was taken.

Both these sections of the investigation were absolute conclusive In two subjects in London a sharp attack ague was induced by puncture by the infected mosquito and Dr Sambon and Dr Low, with precautions as to clothi and as to avoidance of exposure to mosquitoes at the feeding times—namely, just after sunset and after sunrise sojourned through the fever season with impunity It is n too much to hope that these researches will jointly give definiteness and a purpose to attempts made to deal in effective way with one of the greatest scourges of mankin But it is not in prophylaxis only that the elucidation of th life history of malaria has been useful Slipshod use of th term malaria has been responsible for many culpable blunders in diagnosis so that many illnesses have been described as malarial which had no claim whatever to this designation. We also see now that the specific effect of quinine on true malaria is most definite when it reaches the blood as soon as possible after the sporulation of the amœbæ has taken place and the young organisms have escaped from the corpuscles into the serum. We realise again that the anæmia, which may come perilously near to being pernicious as the result of the corpuscular destruction, may still persist after the organisms have disappeared, and that it is in this condition that arsenic finds its chief utility We are still in the dark as to the true relation to malaria of that mysterious disease blackwater fever which has so much in common with the mild paroxysmal hæmoglobinuria of our own climate. But its refractoriness to quinine is quite in harmony with the hitherto negative results as to the presence of malaria parasites in the blood.

MALTA FEVER.

In Malta or Mediterranean fever we have another illustration of how complete exhaustive pathological investigation has led to the rational separation of a given disease from every other The discovery by Bruce of the life-history of the micrococcus melitensis settled once for all the specific nature of this intractable but not very fatal illness and separated it entirely from typhoid fever and malaria.

ACUTE RHEUMATISM

The microbic origin of acute rheumatism was strongly maintained at the meeting of this Association as far back as 1887 by Dr A. Mantle, and its clinical analogies with other infective diseases have been repeatedly set forth. The recent researches of Dr F J Poynton and Dr A Paine seem to have established the existence of a specific diplococcus in the blood in the valves of the heart, in the pericardial exudation, in the joints, and in the subcutaneous nodules of acute rheumatism. From pure cultures of this organism intravenous inoculations in rabbits have been followed by clinical manifestations and by non suppurative lesions similar to those with which we are familiar in acute rheumatism. This seems to be a real contribution to the natural history of the disease and when we have learned something about the rheumatic toxins and about the changes which supervene upon their formation we shall probably get a more satisfactory explanation of the action of the salicylates than is at present forthcoming and we may hope for further light as to the treatment of the complications and refractory forms of this common disease.

THE DIFFERENTIATION OF MENINGITIS.

Bacteriology has done a great deal towards the elucidation of the somewhat confused groups of meningitis. Setting aside the septic cases which arise in connexion with otitis and bone disease and injury as well as those severally dependent upon syphilis and tubercle, there remain (1) the epidemic cerebro-spinal fever in which the characteristic organism is the diplococcus intracellularis (2) the rapidly acute forms, often vertical but sometimes cerebro-spinal, which are associated with pneumonia empyema, and ulcerative endocarditis in which the pneumococcus is the characteristic organism and (3) the sporadic subacute form especially found among young children often limited to the posterior region of the base of the brain but sometimes also spinal, which is usually unaccompanied by any visceral disease whatever In this form Dr G F Still has isolated a diplococcus allied to that of the cerebro-spinal fever but with some definite differences.

There is scarcely any group of diseases in which the resources of therapeutics have been so discouraging It is true that in the first and third of these forms there have been a certain number of recoveries, and although for my part I would not relinquish the use of mercury yet it seems doubtful whether drugs have played any important part in the recovery of the successful cases. Although lumbar puncture and drainage from the cervico-occipital region have temporarily relieved pressure symptoms they cannot as yet be strongly urged as curative measures. May we not reasonably hope that serum therapeutics will one day find some tangible success in this group of intractable diseases? The late Dr J W Washbourn whose premature loss we all lament, had succeeded in making an anti pneumococcic serum and it has also been prepared and used in Italy But the results hitherto obtained, so far as pneumonia is concerned, are inconclusive. I am not aware that there is evidence as to its effect in the form of meningitis depending on the pneumococcus

"ORGANOTHERAPY"

Dr Washbourn was cut down in the beginning of his prime, but we have lately lost another physician in the ripeness of years after a long and distinguished career With the name of Dr W M. Ord must always be associated the merit of having given the first systematic and detailed account of the disease which he called by the name of 'myxœdema. As you will remember it was Gull who in 1873, gave the first clinical description of this malady and in his brief and striking paper with remarkable insight he recognised its affinity with cretinism. But Ord made an elaborate investigation both pathological and clinical of several cases and described the atrophic condition of the thyroid gland. And then came a wonderful series of researches. Reverdin and Kocher showed that the outcome of surgical removal of the thyroid for various diseases was the unlooked for cachexia strumapriva Horsley proved that myxœdema could be experimentally produced in monkeys by removal of the healthy thyroid The various attempts to ingraft the thyroid failed from absorption, but presently George Murray proved that hypodermic injections of extract of fresh thyroid were followed by subsidence of the symptoms of myxœdema, and finally Mackenzie and Fox showed that the gland could be equally advantageously administered when taken by the mouth. The analyses of Hutchison and others will probably pave the way to a still further simplification by indicating which are the really efficient constituents of the gland material and some of the alterative effects in diseases other than myxœdema may perhaps be explained by the unexpected organic combination of iodine which is found to be present in this gland. The relation to exophthalmic goitre, though not yet satisfactorily worked out, is clear enough to show where true lines of fruitful investigation will almost certainly lie. The investigations of Schäfer and Oliver on the suprarenal body have revealed to us the existence of an internal secretion concerned apparently in maintaining the tone of muscular tissues generally and especially of those of the vessel walls. And although they have not yielded a cure for Addison's disease they appear to have given us a hæmostatic agent of considerable local potency

HOW ADVANCE MAY BE MADE IN THE FUTURE.

Hitherto we have stood on a more or less solid basis of established fact, though there have been many gaps in our knowledge, but it would be interesting to forecast a few of the probable directions in which research in the forthcoming generation is pretty certain to add to the common stores With regard to nervous diseases it seems almost certain that some of the acute types will be brought still more into line with the specific fevers Anterior poliomyelitis, for example, which occasionally affects two or three members of a family almost simultaneously and which shows some striking relationships to the exanthemata, will almost certainly prove to be an acute infective disease. The nervous sequelæ and complications of the exanthemata are a mine of clinical wealth and suggestion. For they point not only to disseminated foci of cerebral and spinal hyperæmia and extravasation but also to later changes at first insidious but sometimes far reaching dependent on the dissemination of the toxic products of bacillary growth. It may well be that more developed clinical observation may elicit that in the long latent period which we have assumed to exist between an infective disease and its sequelæ there has been a real continuity of morbid process translateable by signs and symptoms which one day will be obvious enough. If locomotor ataxy for instance be, as we believe the remote outcome of specific disease it will be strange indeed if the latent period does not reveal some intermediate clinical and pathological changes. The great group of peripheral neuritis, towards the elucidation of which we are pre-eminently indebted to the Manchester School (and notably so within the last year) is indeed a meeting place for many etiological factors but it is especially suggestive as showing the parallel effects produced by toxins which are the outcome of bacillary activity and by inorganic and organic material introduced by way of the alimentary tract and perhaps by poisonous products elaborated in the body itself by faulty metabolism

Now with respect to the therapeutics of these diseases the elucidation of their natural history has unquestionably done a great deal by teaching us what cause to remove and so to prevent the further extension of the malady, even in some cases up to a fatal issue. Still, it must be confessed that some members of the group show a singular tenacity in going through a certain evolution, even when the peccant cause has been removed This may seem a disparagement of my original thesis, but knowledge is always justified, and it is something to be able to say that although remedies have not hitherto materially modified the process, yet that the cause having been removed we are tolerably certain that, provided there is no extension to the medullary centres, the cycle will come to an end and that recovery will ultimately be complete Further elucidation may yet show a definite method of shortening the morbid process But if the more complete knowledge of the natural history of these and other obscure nervous diseases does not in the immediate future pave the way to definite antidotes for them it will at least save us from many a blunder We shall learn to leave for a time the morbid processes severely alone and to concentrate our therapeutic efforts on food and on the improvement of the general metabolism of the patient. Can there be any reasonable doubt that we are on the eve of a fuller elucidation of cancer, and that when the history of the organism which we suspect to be behind it has been learned then the fragmentary and isolated pieces of knowledge which have been painfully and slowly acquired during past generations will slip into their proper places like the blocks in the puzzle of a child? But if the history of previous discoveries in our science goes for anything this, again, will be an instance of the convergence of work of experimental pathology, biology and chemistry, and of clinical medicine and surgery in their widest connotations

Gentlemen I have finished my task I have tried to drive home the thesis that the advances in the treatment of disease have been real and satisfactory in proportion as they have been harmonious with the complete knowledge of the natural history of disease I have given various instances in support of this thesis and others could be given If we are agreed, what is our duty arising out of this conviction? Surely, that we ought to do all that in us lies to maintain, to develop and to defend experimental research in alliance with clinical work. Our countrymen are wakening from their complacency and are beginning to realise that in our great industries it is imperative, if we would keep our place, that well directed scientific research should be liberally and steadily maintained And shall it be said that in the care for the life and health of the community, the noblest and most precious of all industries, we are to be left crippled and poverty-stricken by the absence of suitable equipment?

We need trained workers not only in our great university laboratories, which are more or less efficiently equipped, but in every large centre of population it is essential that there should be those who are capable and ready to bring special knowledge to bear on the problems of the public health, and that there should be the necessary means to enable the work to be done It is not the genius of the English people to look to the State to do everything Whoever reflects on the trend of political thought must see that more and more devolution of the national work will go to the municipalities of the country Let us carry the municipalities with us in an enlightened crusade That the public bodies are ready to do the right thing so far as their powers permit and if the plans suggested are practicable is abundantly manifest in this and other great towns And for far reaching researches in the advancement of pathology which lie beyond the proper limits which the municipal bodies could consider may we not look to the generosity of Englishmen? How much has been given for hospitals and charitable institutions but how little for the endowment of research which will help to lengthen human life and to mitigate its physical ills. The British Medical Association has an honourable record in its yearly series of timely and generous grants to individual workers for special research, and some invaluable work has been fostered and helped in this way Might it not in the future seek to coöperate with municipal bodies and through its widespread local branches supply the stimulus and perhaps the pecuniary assistance required to push forward investigation in local laboratories and to afford the direction, encouragement, and countenance which solitary workers so much need. Let us fain hope that the day may come when to the other beneficent functions of this Association there may be added some form of systematised, continuous, and widespread local organisation for the scientific study of the problems of disease.

Five Clinical Lec

ON

THE CAUSATION AND PREVENTION
PHTHISIS.

BY BYROM BRAMWELL, M.D., F.R.
F.R.S. EDIN.,

PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY, &c.

LECTURE V.[1]

GENTLEMEN,—Another argument which has been advan against the compulsory notification of phthisis is that would not work It is argued that there is no likelihood its being efficiently and satisfactorily carried out in th country, that there would be insuperable difficulties in carrying it out in practice, that it would put unj hardships upon phthisical patients since it would in instances lead to their losing their employments, that it would alienate the public in regard to measures of which cannot succeed unless they have the support of public opinion, and that it would place insuperable hindrances in the way of the early treatment of the disease on which the arrest of its future progress and its cure so largely depend. A number of different and very weighty objections are contained in these statements which must be considered individually

Whether a scheme of compulsory notification for phthisis would work or would not work in practice (whether it could or could not be efficiently carried out in this country and whether there would be or would not be insuper objections to carrying it out in practice) entirely, or certainly, very largely, depends upon the nature of the system of compulsory notification, or rather upon the nature of the action (the preventive measures) which would follow upon such notification and the methods adopted for carrying such action into effect I admit, of course, that if phthisis were included under the Infectious Diseases (Notification) Act of 1889, with the object and intention that the same measures of prevention which are habitually applied to the diseases scheduled or included under that Act should be applied to phthisis, the scheme would not work. This argument I have already met. I have pointed out that the restrictive and preventi measures which are required in the case of phthisis a altogether different from, and very much less stringent tha the restrictive and preventive measures which are required in the case of the contagious and infectious scheduled under the Act of 1889, and further, it is essential to remember that restrictive measures would only be required in a limited number of cases, for, as the Board of Health of the city of New York puts it "The sanitary supervision of phthisis should be considered largely on the merits of individual cases and conditions or of classes of cases and conditions." The question is not whether phthisis should be included under the Infectious Diseases (Notification) Act of 1889 with the intention that the same preventive measures which are applied to the diseases scheduled and included under that Act should be applied, but whether it is or is not advisable to make the notification of phthisis compulsory in order that the measures which are advisable and specially adapted for its prevention—i e, for the prevention of phthisis—may be applied In other words, Is it poss to devise a scheme of compulsory notification for phth which would work in practice? The answer is that such scheme is in actual operation in the city of New York Jan 19th, 1897, the following amendment (Section 225) the Sanitary Code of New York was adopted by the Board Health of New York and the following code of instruction was issued to every practising physician in the city :—

CIRCULAR OF INFORMATION TO PHYSICIANS REGARDING THE MEASURES ADOPTED BY THE BOARD OF HEALTH FOR THE RESTRICTION AND PREVENTION OF TUBERCULOSIS IN THE CITY OF NEW YORK.

It is well known to the physicians of the City of New York that for a number of years the Health Department has been earnestly engaged in the study of tuberculosis, the most widespread and fatal disease occurring in this city and in the initiation of such measures for the curtailment of its ravages as seemed practicable and imperative.

---

[1] Lectures I, II, III and IV were published in THE LANCET of July 5th (p 6), 12th (p 61), 19th (p 132), and 26th (p 200) 1902 respectively

From the beginning of this work the Board of Health has recognised the fact that while tuberculosis is unquestionably a communicable disease yet the liability to its transmission may be so greatly diminished by simple precautions as to sharply separate it from those diseases properly classed as contagious. It is to be remembered that while tuberculosis is always the result of direct infection yet it is far less readily communicated than such diseases as small pox, scarlatina, &c., and that if proper sanitary conditions can be secured in each case there is little danger of the transmission of the disease to others. *The sanitary supervision of this disease should, therefore be considered largely on the merits of individual cases and conditions or of classes of cases and conditions* [No italics in the original.]

Thus in its "Circular of Information for Consumptives and those living with them" the Health Department has emphasised these facts That a person suffering from consumption may if his sputum be properly cared for pursue his usual avocations without endang[illegible] others that the disease is often curable; and that early recog[illegible] greatly enhances the chances for recovery As this relatively inno[illegible] character of pulmonary tuberculosis is absolutely dependent up[illegible] intelligent observation of simple and obvious measures for the di[illegible] of the sputum, the earlier efforts of the board were largely educational or directed to the collection of knowledge regarding [illegible] cases, or groups of cases as seemed to constitute the most [illegible] menace to the welfare of the public

On Feb 13th, 1894 the Board of Health passed a series of resolutions designed to assist in the accomplishment of its aims in the suppression of tuberculosis. One of these resolutions involved the reporting of certain classes of cases of tuberculosis, and in compliance with it 4166 cases were reported in 1894 5818 in 1895 and 8344 in 1896 and the Department was enabled, without opposition and without the imposition of hardship upon individuals to extend its educational influence and to protect a large number of persons from risks which without such measures, must inevitably have led to further serious spread of the disease

In order to more firmly establish and to extend the work carried on under the measures above-mentioned on 19th January 1897 the following amendment to the Sanitary Code was adopted by the Board of Health :—

Sec. 225. That pulmonary tuberculosis is hereby declared to be an infectious and communicable disease dangerous to the public health It shall be the duty of every physician in this city to report to the Sanitary Bureau in writing the name, age, sex occupation, and address of every person having such disease who has been attended to by or who has come under the observation of such physician for the first time within one week of such time. It shall also be the duty of the commissioners or managers or the principal superintendent, or physician of each and every public or private institution or dispensary in this city to report to the sanitary bureau in writing or to cause such report to be made by some proper and competent person the name, age sex, occupation and last address of every person afflicted with this disease, who is in their care or who has come under their observation within one week of such time It shall be the duty of every person sick with the disease and of the authorities of public and private institutions or dispensaries to observe and enforce all the sanitary rules and regulations of the Board of Health for preventing the spread of pulmonary tuberculosis.

This section of the Sanitary Code in effect gives legal force to the measures which had been provisionally adopted by the board under resolutions three years earlier It will be noted that in this section of the Sanitary Code pulmonary tuberculosis is classed as an "infectious and communicable disease, dangerous to the public health" *and is not grouped with the contagious diseases* [No italics in the original]

The following circular of information to physicians regarding the measures adopted by the Board for the restriction of this disease was originally published in 1894 and was then forwarded to every physician practising in this city It is now re-issued by the Department after being slightly modified to correspond with the provisions of the above amendment. It describes, in sufficient detail for the information of physicians the purpose of the Health Board and the scope of its work in relation to tuberculosis. The circular follows :—

The communicability of pulmonary tuberculosis has been so thoroughly established, and is now so generally recognised by the medical profession throughout the world that the Board of Health of New York City has determined to take active steps looking toward its prevention in this city and has adopted the following measures —

First. The Health Department will hereafter register the name address, sex and age of every person suffering from tuberculosis in this city so far as such information can be obtained and will require that all physicians furnish such information to the Sanitary Bureau as provided in the above section of the Sanitary Code (postal cards for reporting cases of tuberculosis will be forwarded on application) *This information is solely for record and in no instance will visits be made to such persons by the inspectors of the Department, nor will the Health Department assume any sanitary surveillance of such cases unless the person resides in a tenement house or lodging house (unless in other cases the attending physician requests that an inspection of the premises be made) In no case where the person resides in a tenement house or lodging house will any action be taken if the physician requests that no visits be made by inspectors and is willing himself to deliver circulars of information or to furnish such equivalent information as is required to prevent the communication of the disease to others* [No italics in the original]

Second When the Health Department obtains knowledge of the existence of cases of pulmonary consumption residing in tenement houses or lodging houses (unless the case has been reported by a physician and he requests that no visits be made) inspectors will visit the premises and family will leave circulars of information, and instruct the person suffering from consumption, or the family as to the measures which should be taken to guard against the spread of the disease and, if it is considered necessary will make such recommendations for the cleansing or renovation of the apartment as may be required to free it from infectious material

Third In cases in which it comes to the knowledge of the Health Department that rooms or apartments in tenement houses lodging houses, &c., which have been occupied by a consumptive, have been vacated by death or removal an inspector will visit the premises and, when necessary will direct the removal of infected articles such as carpets, rugs, bedding &c. for disinfection and will make such written recommendations to the Board as may be required regarding the cleansing and renovation of the rooms or apartments An order embodying these recommendations will then be issued on the owner of the premises and compliance with this order will be enforced No persons other than those there residing at the time will be allowed to occupy such rooms or apartments until the order of the Board has been complied with Infected articles, such as carpets rugs &c., will, when necessary be removed by the Health Department, disinfected and returned without charge to the owner

Fourth For the prevention and successful treatment of pulmonary tuberculosis, it is of vital importance that a positive diagnosis be made at the earliest possible moment In order that the assistance afforded by bacteriological examinations of the sputa may be at the command of physicians in all cases, *not under treatment in hospitals* the Health Department is prepared to make such bacteriological examination if samples of the sputa, freshly discharged are furnished in clean wide-[illegible] anied by a blank giving the [illegible] it, the duration of the disease, [illegible] nding physician. Bottles for [illegible] o be filled in can be obtained [illegible] ations for the distribution and [illegible] a cultures After the sputum [illegible] he accompanying blank filled [illegible] ill be collected by the Health [illegible] croscopically and a report of the examination forwarded to the attending physician free of charge *The information regarding cases of pulmonary tuberculosis obtained by the Health Department through such bacteriological examinations of sputum is solely fo* [illegible] *monary tuberculosis thus reported will* [illegible] *the Health Department nor will cir* [illegible] *without the special request of the attending physician.* [No italics in the original]

Fifth. The authorities of all public institutions such as hospitals dispensaries asylums prisons, homes &c. are required to furnish to the Health Department the name sex age occupation and last address of every consumptive coming under observation within seven days of such time The premises occupied by all persons reported by the authorities of public institutions as suffering with pulmonary tuberculosis will be visited by inspectors of the Health Department and such action taken as seems necessary

[illegible] physicians in this city coöperate with the Board in an intelligent and sustained effort to restrict the ravages of this, the most prevalent and formidable disease with which we have to deal

In speaking of the results which have so far been attained by compulsory notification Dr Hermann Biggs the medical officer of health of New York, states —

> In nearly one-half of the cases occurring in many parts of the tenement house districts of the city it is found that more or less efficient precautions are being taken and there has been a most gratifying increase of knowledge and intelligence which affords the greatest promise for the future

The following objections have been urged against this—the New York—system of compulsory notification — That it is a system which is compulsory in a very limited sense that the success of the system depends largely on the good will or the expressed desire, of medical practitioners whether any official sanitary control is to be exercised or not that it is for any purpose of prevention that can be deemed applicable to the population generally a voluntary system not a compulsory system and that in this country no statutory effect could be given to a similar system under the present law

In answer to these objections I would say —That the New York system seems to me to be a system of compulsory notification which is eminently well adapted for the special peculiarities of phthisis—and that is what is required that if the system is considered to be satisfactory statutory effect might easily be given to it in this country by altering the law (if fresh legislation is necessary before it can be adopted and applied) and that, allowing for the differences which obtain between phthisis and the infectious and contagious diseases scheduled under the Act of 1889 it appears so far as its practical working is concerned to be very similar to the compulsory system which is employed in Edinburgh for the notification of all the contagious and infectious diseases included under the Infectious Diseases (Notification) Act of 1889

In the year 1879 10 years before the Infectious Diseases (Notification) Act of 1889 was passed the municipality of Edinburgh made the notification of infectious and contagious diseases compulsory They consequently did not think it necessary to adopt the Infectious Diseases (Notification) Act of 1889 The clause (208) of the Edinburgh Municipal and Police Act of 1879 which refers to the notification of infectious diseases is as follows —

> In order to secure more prompt action in dealing with infectious diseases every medical practitioner practising within the burgh shall within 24 hours of the same coming to his knowledge report to the

medical officer of health every case of cholera, typhus fever, typhoid fever, diphtheria, small pox, scarlet fever (scarlatina), and measles (in this Act characterised as infectious or contagious diseases), occurring in his practice and stating the house or place where the patient is being treated under a penalty not exceeding 40s, and if it be found on inquiry by the medical officer of health that the diagnosis of such practitioner was correct such practitioner shall be paid the sum of 2s 6d for each case reported and verified as aforesaid and in order to facilitate the making of such report every such practitioner shall from time to time, be furnished, on application to the medical officer of health, with printed forms stamped for postal transmission

The printed forms which were then issued, and which are still issued, to every medical man in practice in the city, are as follows —

No EDINBURGH MUNICIPAL AND POLICE ACT, 1879

To Medical Officer of Health, Police Chambers

There is a case of
at, ...
.. 18
No immediate attention required ..
Signature

Under this—the Edinburgh System of *Compulsory* Notification for Infectious and Contagious Diseases—the medical attendant is responsible (1) for the notification of cases of the contagious and infectious diseases enumerated above, and (2) is virtually responsible for seeing that, in those cases in which he does not demand the assistance of the medical officer of health, the necessary preventive measures (isolation, disinfection, &c.) are carried out, for, as a matter of fact, the medical officer of health does not take any steps to ascertain that the diagnosis is correct and does not interfere unless his assistance is demanded by the medical man in attendance on the case, or unless he (the medical officer of health) should for any reason conclude that such interference (which had not been demanded by the medical man in attendance) is required. Of course, if there were reason to doubt the correctness of the diagnosis, or to suppose that the medical attendant did not appreciate the gravity of the case or that he was unable without the assistance of the medical officer of health to carry out the necessary preventive measures, the medical officer of health and the sanitary authority would interfere, in other words, hey have the power of interfering in every case and of aking any steps for verifying the diagnosis, the removal f patients, the disinfection of houses, &c., which they he medical officer of health and the sanitary authority) ay deem it advisable or necessary to take But such terference (either for the verification of the diagnosis, for disinfection, or for the removal to hospital), except in those cases in which it is demanded by the medical attendant, is rarely found to be necessary and, as a matter of fact, rarely takes place In the case of phthisis, such interference unless it was demanded by the medical attendant, would be very rarely, if ever, required, except in the poorer districts and the overcrowded parts of the city By the Edinburgh system every medical man who is in attendance on a case of contagious or infectious disease may, practically speaking, be considered to be for the time being in the service of the local sanitary authority Unless the medical officer of health and the local sanitary authority should see fit to interfere he is entrusted with the sole responsibility of the case and is virtually responsible for seeing—for by refusing to call in the aid of the medical officer of health he virtually takes upon himself the responsibility of seeing—that the proper measures for isolation, disinfection, and protecting the healthy persons who have been, or who may be exposed to infection (i e., who are living with the patient) are carried out. The information conveyed by this system of notification to the medical officer of health is regarded by him as confidential, and, as a matter of fact, is strictly confidential, unless any reason to take action should arise. The experience of Edinburgh shows that such a system of compulsory notification works well. Sir Henry Littlejohn informs me that it "has worked in this city of medical men without a hitch," and that it is efficient in the case of all of the infectious and contagious diseases included under the Act of 1899 *A fortiori*, therefore, there is every reason to suppose that it would work well and that it would be efficient in the case of phthisis, provided, of course, that the powers with which the sanitary authority were endowed and the action which the sanitary authority would take subsequently to the notification were modified and adapted to the special requirements of the disease (phthisis)

Such a system as that which is in actual operation in New York for the [illegible] notification of phthisis which in its pract[illegible] working (allowing, of course, differences which obtain between phthisis and the and contagious diseases scheduled under the Act of 1 appears to be very similar to that which is in operation Edinburgh for the compulsory notification of the contagio and infectious diseases scheduled under the Infectio Diseases (Notification) Act of 1889 seems to me to admirably well adapted for the compulsory notification phthisis

Everyone allows that it is to the medical men who are in actual attendance on phthisical patients that we must chiefly look, in the first instance at least, for the introduction of preventive measures, it is their duty to and instruct their patients and the persons with whom those patients live as to the preventive measures—the destruction of the sputum, ventilation, cleanliness, &c.—which should be employed, and it is their duty to do what they can to persuade the patients and their friends faithfully and diligently to carry these preventive measures into effect. And I maintain that a compulsory system of notification specially adapted to phthisis would greatly strengthen the hands of the medical profession and enable the medical practitioner in attendance on a phthisical patient to insist with much more chance of success at present the case that in those cases in which his advice unbacked by such a system, is ignored the necessary preventive measures *are* carried into effect. In this connexion the following statements of Professor G Sims Woodhead and Dr A. Newsholme seem to me to be of great importance.

Professor Woodhead says —

> In regard to the prevention of phthisis spreading from human patients I must frankly confess that I am greatly in favour of compulsory notification and I am in favour of this because I think it one of the means of impressing upon the public, and even in some cases upon ourselves the fact that there is danger of the spread of infection from tuberculous patients, unless proper precautions be taken by the patient and his friends to destroy all excreta and secreta that may contain tubercle bacilli! The very fact that we consider it necessary to speak of tuberculosis as a notifiable disease should render our task of disinfecting a patient and his surroundings a much one.[2]

Dr Newsholme says —

> It will be argued that sanitary authorities (local or central) already have power under existing laws to diminish the operation of respiratory impurities and industrial dust, and possibly, to a less extent, of damp and dark houses That is a plausible opinion which will probably continue to find favour with those who have no practical experience of local sanitary tion but it will not bear critical study Even supposing that there are ample legal enactments against overcrowding and dust, it must be admitted that the knowledge of a case of phthisis in connexion with overcrowding or a dusty occupation will enormously strengthen our hands in securing the adoption of the necessary remedies. Many nuisances cannot now in many districts be remedied because support is not obtained from the sanitary authority or the magisterial bench Would not a medical certificate that a case of phthisis had occurred in the house where the nuisance was found turn the balance in favour of reform?" And again Even in well-organised districts, a house is seldom inspected oftener than once a year and it must be evident that if we knew of a case of phthisis in a house immediate cognisance could be taken of, and action adopted in respect of conditions favouring phthisis which under other circumstances would probably be delayed for many months and which might have to be entirely omitted in the present state of education of the public. Our leverage in sanitary operations would be enormously increased if a considerable proportion of the cases of phthisis were notified Quite apart from the adoption of special precautionary measures against infection the localisation and remedying of house defects as to cleanliness crowd and dampness would amply repay for all attempts at the notifica of phthisis

Under a system of compulsory notification such as advocate (the New York system or the Edinburgh system compulsory notification applied and adapted to phthisis) th medical practitioner would be responsible for the notific tion, he would be obliged to report to the medical officer o health every case of phthisis immediately it came under his observation, he would receive a fee for such notification, he would at the same time indicate whether the assistance of the medical officer of health was required—in other words, whether the sanitary surroundings of his patient were such as to *necessitate* the intervention of the local sanitary authority or not, and he would, during the subsequent progress of the case—i.e., so long as the patient re mained under his observation, be required to report to, in other words to request the aid and of the sanitary authority whenever such intervention seemed urgently required For each such additional he should, I think, be paid an additional fee. The medical officer of health would in this way be informed of the locality of every case of phthisis as soon as it came under medical observation, and he would be at the same time informed by a highly skilled inspector—the medical man in attendance—whether the surroundings of the patients were in a sanitary or an insanitary condition and whether the active intervention of the medical officer of health (i.e., of the sanitary authority) were required or not. Further, he would be kept in touch with all the cases of phthisis which had been notified so long as they continued under the care of the medical practitioners who had notified them. The migratory cases should, I think, be again notified whenever they came under the observation of another medical practitioner and for such second or subsequent notifications another or perhaps a reduced notification fee should be paid. It cannot, I think, be doubted that the information obtained in this way would be of the greatest possible value to the medical officer and to the sanitary authority in dealing with the disease.

---

[2] Edinburgh Medical Journal

Another objection urged against such a system of compulsory notification of phthisis as I have sketched out above is that frequent inspections would be necessary, that a large staff of inspectors would be required, and that intolerable friction would occur as the result of such inspections.

In answer to this objection I would say firstly that under such a system as the Edinburgh system of compulsory notification a comparatively limited amount of inspection would be required, for the medical attendants who report the cases would, practically speaking, be inspectors. In those cases in which they did not demand the assistance of the sanitary authority the medical attendants would, virtually speaking, make themselves responsible for seeing that the necessary precautionary measures were satisfactorily carried out so far as the circumstances and surroundings of the patient would allow, and they would, without doubt, usually report that no assistance from the medical officer of health and the sanitary authority was required; for if—as is the fact—the assistance of the medical officer of health and of the sanitary authority is rarely demanded in the case of the contagious and infectious diseases scheduled under the Act of 1889 such assistance would be very much less frequently demanded and required in cases of phthisis. Secondly, that under the Edinburgh system, and so far as I know under the New York system, friction does not occur. On this point Dr. Newsholme states:—

> The inquiries resulting from notification would in nearly every instance be made at the patient's home, not at his place of business, and with proper provisos there need be, and would be, no interference with business. In the final analysis, if any must suffer ought it not to be one rather than many? But, I repeat, there is not the slightest necessity for anyone to suffer through notification, and the medical officer of health through whose action such suffering arose would speedily find his position so uncomfortable that the indiscretion would not be repeated.
>
> Speaking from 15 years' experience of local sanitary administration in London and Brighton, I have no hesitation in stating my emphatic opinion that the visitation of phthisical houses in which such visits are desirable is not only perfectly practicable but is of as great importance to the public weal as similar visits in houses where diphtheria or enteric fever has occurred. I protest against the assumption which appears to be so commonly entertained that the official work of the medical officer of health is confined to the seven chief zymotic diseases and that tubercular diseases which cause 60 per cent. more deaths than the aggregate of these seven zymotic diseases and are much more capable of being prevented than are several of them are outside the sphere of his official action.

And thirdly, that even if a considerable amount of inspection were required the necessary staff of skilled inspectors (medical men acting under the immediate supervision of the medical officer of health) ought, in my opinion, to be provided by the local sanitary authority and paid for out of the rates. Even the limited amount of inspection which would be required under the system of compulsory notification which I advocate would no doubt involve a large expenditure of money—at all events for some years to come—but, as I have already pointed out, the object to be obtained is well worth paying for. The financial objection has already been considered.

Another objection which I have heard urged against the compulsorily notification of phthisis is the difficulty of diagnosing phthisis in its early stages and the friction which would consequently arise both between the patient and his doctor who made the notification or suggested that the case should be notified and the medical man originally in attendance and another medical man who would be certain in many cases to be called in when the patient learned that he (the medical man first in attendance) proposed to notify the case.

The answer to this objection is that no case of phthisis would be notified unless it had been proved by microscopical examination that tubercle bacilli were present in the sputum, a fact which would, of course, put the diagnosis beyond dispute. This is one of the reasons why I think it is the duty of the sanitary authority to provide laboratories, or to make arrangements with existing laboratories, for the testing and reporting on the sputum.

Another objection raised against such a scheme of compulsory notification as has been suggested above is that if the phthisical patients refused to carry out the necessary preventive measures (destruction of the sputum, &c.) the sanitary authority would be powerless unless they were to insist upon the removal of such (dangerous) phthisical patients to a hospital, and consequently that the sanitary authority, if it had the power to insist upon such removal and were to insist upon it, would require to provide the necessary hospital accommodation for such cases.

On this point Dr. Hermann Biggs says:—

> A great obstacle to practical success lies in the fact that the necessary precautions cannot, in a large number of cases, be adopted without the establishment, under the direct control of the Health Department, of special hospitals for the treatment of this disease, and hence numerous instances are met with every week "in which members of many households, numerous inmates of crowded tenement houses, employés in dusty and unventilated workshops, and many others ....." reject all proffered assistance and instruction. In such cases sanitary suggestions are futile and removal to a hospital constitutes the only effective action.

This is, I admit, the great practical difficulty in the way of effectually dealing with the disease. The fact must, I think, be recognised and faced that if a phthisical patient refuses to carry out the necessary preventive measures (for the destruction of the sputa, &c.) he is in some degree a source of danger to the healthy (unaffected) persons with whom he is in immediate contact and to the public at large. I admit, with the French Commissioners who have urged this as their most important argument against the compulsory notification of phthisis, that the only logical method of dealing with this difficulty is to give the sanitary authority power to consign such cases of phthisis (or such cases as are considered dangerous) to a hospital and to retain them in hospital until they agree to carry out the necessary preventive measures.[8]

I have already stated that while, in my opinion, it is not the duty of the sanitary authority to provide hospital accommodation for the *treatment* of cases of early phthisis—i.e., to provide and keep up sanatoriums—it is the duty of the local municipal and sanitary authorities (if a real attempt is to be made to reduce the prevalence of phthisis to the lowest possible attainable dimensions) to provide out of the rates, either by themselves or conjointly with the Poor-law authorities, hospital accommodation for those cases of phthisis in which the patients either from (*a*) the insanitary nature of their surroundings combined with their inability to carry out the necessary preventive measures or (*b*) the insanitary nature of their surroundings combined with their refusal to carry out the necessary preventive measures are *a distinct source of danger* to the healthy persons with whom they are in immediate contact, and therefore to the community at large. Theoretically speaking, cases of this kind ("dangerous" cases of phthisis as I term them) ought to be sent to hospital, and personally I am strongly in favour of giving to the sanitary authorities the compulsory powers which are necessary for dealing with such cases, for such compulsory powers are, I think, necessary if our preventive measures are to be thorough and effectual (i.e., in order to reduce the prevalence of the disease to the lowest attainable limit). Further, I believe that a little compulsion judiciously applied (i.e., applied in the worst and most glaring cases) would, in the course of a short time, cause a very substantial diminution in the number of cases in which the patients refused to carry out the necessary (easy and simple) preventive measures, though their number would even then continue to be very great.

But while making this statement I do not mean to suggest

---

[8] *Le seul moyen logique et efficace contre le tuberculeux qui ne peut ou ne veut détruire ses crachats ou ses déjections bacillifères c'est l'internement dans un hôpital.* Les Drs. Holmboe et Hansen chargés de rédiger pour la Norvège un projet de loi contre la tuberculose n'ont pas hésité. Voici le 2e paragraphe de l'article VI. de leur projet: "Dans le cas où la situation du malade ne lui permettrait pas de prendre les mesures nécessaires, ou que le malade par suite de mauvaise volonté aurait négligé de suivre les injonctions de l'autorité médicale celle-ci est autorisée à ordonner le transport immédiat dans un hôpital."

[illegible] of phthisis in which the patients [illegible] must immediately be [illegible]lling to carry out the necessary [illegible] numbers are far too great for [illegible] the provision, in the first instance, of [illegible] limited amount of hospital accommodation sufficient to receive the worst and most aggravated—i.e., the most dangerous—cases. I admit that it would be necessary to apply such compulsory powers cautiously and to a limited extent, at all events in the first instance. But while this is my individual—I would add my strong and deliberate—opinion it must be allowed that neither the public, the profession, nor many of the warmest advocates of compulsory notification seem as yet prepared to consent to such compulsory notification. Dr Newsholme, for example, states —

> In practice, segregation of the phthisical patient, except where it is voluntarily undertaken in the interest of the patient, is entirely out of the question

I have already dealt with the objection that the provision of such hospital accommodation would necessitate a very large expenditure of money, and have stated that unless the public and their representatives—the municipal and sanitary authorities—are prepared to face a large expenditure of money it is in my opinion, useless and Utopian to talk of attempting to stamp out and eradicate phthisis and other forms of tuberculous disease, or to expect that the maximum amount or anything like the maximum amount, of prevention which is attainable with our present means of prevention will ever be reached.

Another objection, which is practically the same as that which has just been considered, is that the compulsory notification of phthisis would interfere with the liberty of the subject to such an extent that it would not be accepted by the people of this country. This objection seems to be based upon the supposition that if the notification of phthisis were made compulsory the same action (restrictive measures) would necessarily follow as in the case of the contagious and infectious diseases scheduled under the Act of 1889.

I have, however, already pointed out that the action which would follow the compulsory notification of phthisis would necessarily be very different from the action which follows the compulsory notification of the infectious and contagious diseases scheduled under the Act of 1889, since the reasons for notification are entirely different in the two cases—I mean the contagious and infectious diseases scheduled under the Act of 1889 on the one hand and the great majority of cases of phthisis on the other—and in those (dangerous) cases of phthisis in which compulsory removal to a hospital is urgently required I see no reason why the public should merely because of their chronicity, though I admit that their numbers would be a great practical difficulty and that for a time at least one would have to be content with dealing with the worst (most dangerous) cases only, object to such compulsory removal, since it would only be practised because the patients were a distinct source of danger to their neighbours and to the community, any more than they object to the compulsory removal of cases of the infectious or contagious diseases scheduled under the Act of 1889. But, as I have just stated, the public do not as yet seem to be prepared to consent to such restrictive measures, though individually I am strongly of opinion that without such restrictive legislation it will be impossible to reduce the prevalence of the disease to anything like the lowest possible attainable limit. Too much weight must not, however, be attached to this admission as an argument against the compulsory notification of the disease, for I submit that the compulsory notification of phthisis would still be of immense benefit even if it did not carry in its train compulsory powers for dealing with (i.e., removing to hospital) those patients whose sanitary surroundings are eminently bad and who are either (*a*) unable or (*b*) unwilling to adopt the necessary preventive measures, though I believe that the benefits which would result from any system of compulsory notification would be considerably lessened if it did not carry with it compulsory powers for dealing with those cases of phthisis which I have termed 'dangerous.'

The next argument—or, rather, series of objections—which has been advanced against the proposal is that the compulsory notification of phthisis would entail great hardships on phthisical patients since it would lead to a large number of them being dismissed from their employments, that phthisical patients who had been dismissed in this way would in future take care not to afford any outward evidence of their malady by the adoption of precautionary measures urged [illegible]terests of the public, that [illegible] would [illegible]quently, after being once dismissed from the employment, avoid consulting another medical practi [illegible] and that a large amount of harm would therefore [illegible] the disease were scheduled under the list of notifiable diseases under the English Act, for the knowledge [illegible] notification would ensue would prevent resort to advice in the early stages of the disease when its [illegible] could be best arrested.

I admit that if the premises on which this argument is based are correct and that if the conclusions which are founded on those premises are accepted they form serious and weighty objections to the compulsory notification of the disease. But, I ask, are these premises these conclusions correct? And my answer is that I do think so. It is argued that "the justification for the that phthisis shall be compulsorily notified lies in the fa that the person in question is suffering from a dangero infectious disorder communicable from person to person." I emphatically protest against, and disagree with, this way of stating the fact that phthisis is an infectious disease which may under certain circumstances be communicated from person to person, for it is, I maintain, calculated to give an altogether erroneous conception of the infect of phthisis and of the danger which a healthy unaffected person runs of contracting the disease from being in contact a person affected with the disease, and it is, therefore, calculated to do harm by unduly alarming the public. In my opinion it would be more correct to say that the justification for the demand that phthisis shall be compulsorily is founded on the belief that it (compulsory notification) is necessary and essential in order to reduce the prevalence of the disease to the lowest attainable point. I allow that if the public are taught, without any qualification, to believe that phthisis is a dangerous infectious disorder communicable from person to person loss of employment would be likely to follow the compulsory notification of the disease. But I emphatically dissent from the unqualified statement that "phthisis is a dangerous infectious disease communicable from person to person." I submit that if the public were made thoroughly to realise and to appreciate the fact that a healthy person who lives or works in close contact with a patient suffering from phthisis runs, practically speaking, little or no risk of contracting the disease, provided that certain simple precautionary measures are carried out (notably the disinfection or destruction of the sputum while it is still moist), such loss of employment would be much less likely to occur than has been supposed. The fact that, provided the sputum is destroyed or thoroughly disinfected while it is still moist, the risk of infection in cases of phthisis is so slight that for practical purposes it may be entirely ignored is of paramount importance. It is of the utmost importance that it should be brought home to the public. The public must be made to understand (1) that phthisis is not dangerous except through the sputum,[4] (2) that the sputum is easily dealt with (disinfected and destroyed), and (3) that if the sputum is disinfected or destroyed while it is still moist and proper precautions are taken in respect to ventilation and cleanliness there is practically no risk of being in contact with a patient affected with phthisis.[5] The latter statement is abundantly justified by the statistics of the Brompton Hospital and by the opinion of numerous weighty authorities. These observations show that even in hospitals specially devoted to the treatment of consumption and filled with phthisical patients the physicians, nurses, and attendants do not acquire the disease, provided that proper attention is given to ventilation, cleanliness, and the disinfection of the sputum. Cornet states "The consumptiv in himself is almost harmless and only becomes harmfu through bad habits."

I of course admit that a healthy person should not sleep in the same bed with a patient suffering from phthisis. I admit that if this condition were enforced a certain number of phthisical patients would lose their employment.

---

[4] In the present connexion I need not refer to the diarrhœa which results from tuberculous ulceration of the intestine since tuberculous ulceration of the intestine does not occur in the early stages of phthisis and since persons affected with tuberculous ulceration of the intestine whether occurring as a late event in the course of ordinary phthisis or as an early event in the course of generalised (acute) tuberculosis are not in a position to follow their employment.

[5] Except through inhaling particles of sputum coughed into the atmosphere, or through kissing, or using a cup [illegible] spoon [illegible]taminated with phthisical sputum

But this is inevitable It cannot be prevented under any circumstances (whether the compulsory notification of the disease is adopted or not) provided that it be granted—and every one, I presume, will grant this—that the healthy (unaffected) members of the community have a right to be protected from infection. It must be remembered that the healthy members of the community and healthy employés have at least, equal rights with the diseased (phthisical) members and diseased (phthisical) employés I therefore maintain that no employer has a right to allow—and the sanitary authorities have no right to permit, if they can prevent it—an employé who is suffering from phthisis to sleep in the same bed with a healthy employé I further suggest—though this is no doubt a debatable question, since the risk that a healthy person runs of being closely associated with a patient suffering from phthisis is a small risk—that no right-minded employer of labour should, if he can prevent it, allow a person who is suffering from phthisis to work in close contact with other healthy employés, unless he (the employer) is satisfied that the proper precautionary measures (for the destruction of the sputum, for ventilation and cleanliness) are carried out, since such preventive measures are, in most cases at all events simple and are easily and readily carried out. I maintain that the healthy members of the public—the large majority—have a right to demand that they should be adequately protected against phthisis, just as they have a right to demand that they should be adequately protected against the diseases scheduled under the Act of 1889 notwithstanding the differences as regards chronicity

I conclude then that if the public were made clearly to understand that there is little or no risk of a healthy person contracting phthisis from being in close contact with a person affected with phthisis, provided that proper precautions with regard to cleanliness, ventilation, and the disinfection of the sputa are carried out, the loss of employment which it is stated would result from compulsory notification would be much less than has been supposed

But I go further than this and I suggest that the compulsory notification of phthisis, instead of being likely to cause the dismissal of phthisical patients from their employments would, on the contrary be likely to maintain them in their employments. My reasoning is as follows. Up to the present time or until quite recently the public have not realised the fact that phthisis is under certain circumstances an infectious disease—i e. capable under certain circumstances of being conveyed from the sick to the healthy Consequently phthisical patients have been allowed to work in close contact with healthy persons, and even to sleep in the same beds with healthy persons, without any special precautions being taken. The great advance in public knowledge regarding phthisis which has recently taken place and which is making rapid progress every day has placed the position on a very different footing The public have been now taught to regard phthisis as an infectious disease. But, as I have already pointed out, this statement requires qualification—it is in short, essential that the public should be also taught that there is practically little or no risk of infection provided the proper precautions are taken and that these precautions are simple and easy Consequently it reasonably may be expected that as soon as the public thoroughly realise that there is a risk of the disease being propagated from person to person unless satisfactory precautions (for the destruction or disinfection of the sputum and as regards ventilation and cleanliness) are taken right-minded employers of labour will not allow persons affected with phthisis to be employed along with other healthy persons and therefore will dismiss persons who are suffering from phthisis, or whom they suspect to be suffering from phthisis from their employment, unless the necessary and simple precautionary measures to prevent infection are taken, and healthy persons will object to be employed in close contact with persons suffering from phthisis, or persons whom they suspect to be suffering from phthisis unless such precautions are taken. But if they (the public, the employers of labour and the healthy employés) are made to understand as they should be made to understand, that there is little or no risk from being closely associated with persons suffering from phthisis provided that the necessary and simple preventive measures (for the destruction of the sputum ventilation and cleanliness) are carried out, and if they realise that by a compulsory system of notification every person who is suffering from phthisis will, as soon as he applies for medical advice be carefully instructed with regard to the necessary preventive measures, and that medical men and the sanitary authorities will do their best to see that such preventive measures are carried into effect, they will feel that they have in compulsory notification and the precautionary measures based thereon a protective measure which is of great benefit to them—which is a distinct safeguard to them. In short, they will realise that with a system of compulsory notification there is much less risk than there would be without a system of compulsory notification of their being associated with patients suffering from the disease. Consequently it may be reasonably expected I suggest that in the future phthisical patients will run less risk of being dismissed from their employments if a system of compulsory notification is adopted than they would do if a system of compulsory notification were not adopted.

Since the foregoing paragraph was written I find that the same opinion has been expressed by Dr Newsholme. He says —

> While writing the above I have heard of the case of a clerk who appears to have been discharged from his post because he was phthisical in connexion with the recent publicity given to the dangers arising from the sputa of such patients If the admirable propagandism of the Association for the Prevention of Tuberculosis is to continue (and we all hope that it will) a certain amount of alarm among those imperfectly informed is inevitable In all probability nothing would be more successful in removing this unreasonable fear (unreasonable when proper precautions are taken) than the knowledge that cases of phthisis are notified to the medical officer of health who has official charge of any necessary precautionary measures

But even granting that loss of employment did occur in a certain proportion of cases are we justified for this reason in concluding that the compulsory notification of the disease should not be adopted? I do not think so. A certain amount of hardship must necessarily result if the prevalence of phthisis and other forms of tuberculous disease is to be reduced to the lowest attainable limit. The few must unfortunately *suffer for the many* Year by year as the *disease* would become eliminated from the population the few would become fewer and fewer If I am right in thinking that it is impossible to reduce the prevalence of phthisis to anything like the lowest possible attainable limit without a system of compulsory notification, if compulsory notification would afford as I hold it would undoubtedly do valuable assistance in the prevention of phthisis and is essential and if our preventive measures are to be thorough and effectual we are surely justified in disregarding however much we may deplore it, the hardship which would be enjoined upon the few The benefit to be gained by the many in my opinion far outweighs the hardship (loss of employment) to the few

Let me next consider whether the compulsory notification of phthisis would have the disastrous effects which it is stated it would have in preventing patients suffering from early phthisis taking medical advice and the necessary measures for the cure of their disease. In considering this question it seems to me essential in the first place to determine whether a healthy person does or does not run a risk of contracting the disease from being closely associated—as, for example, in a workshop, office or shop—with a patient suffering from phthisis. That there is some risk (though I believe in the case of perfectly healthy persons it is comparatively speaking a small risk) unless the proper preventive measures (for the destruction of the sputum satisfactory ventilation, and cleanliness) are taken everyone will, I suppose allow That this risk is greatly diminished and is, practically speaking abolished if such precautions are taken everyone or almost every one, will I suppose, also allow Further it must be admitted that a compulsory system of notification such as I have suggested would in some degree diminish the risk to the healthy employés since it would to some extent at all events ensure that the necessary preventive measures were carried out. Again it must be allowed that the healthy employés have a right to demand either that they should not be employed alongside phthisical patients or that the phthisical patients should be obliged to take the necessary and simple precautions to prevent their being dangerous to their neighbours. I have further suggested that if the public are made to understand that there is practically no risk of associating* with phthisical patients, provided that certain simple and easily carried out precautions are adopted, in the future phthisical patients will if they take such precautions and that sufficient hospital accommodation must immediately be provided for all the cases of phthisis in which the patients are either unable or unwilling to carry out the necessary preventive measures. The numbers are far too great for this All I advocate is the provision, in the first instance, of a certain limited amount of hospital accommodation sufficient to receive the worst and most aggravated—i.e., the most dangerous—cases. I admit that it would be necessary to apply such compulsory powers cautiously and to a limited extent, at all events in the first instance. But while this is my individual—I would add my strong and deliberate—opinion it must be allowed that neither the public, the profession, nor many of the warmest advocates of compulsory notification seem as yet prepared to consent to such compulsory notification. Dr Newsholme, for example, states —

---

* I exclude sleeping with phthisical patients for this as has been already pointed out is attended with some risk

> In practice, segregation of the phthisical patient, except where it is voluntarily undertaken in the interest of the patient, is entirely out of the question

I have already dealt with the objection that the provision of such hospital accommodation would necessitate a very large expenditure of money, and have stated that unless the public and their representatives—the municipal and sanitary authorities—are prepared to face a large expenditure of money it is in my opinion, useless and Utopian to talk of attempting to stamp out and eradicate phthisis and other forms of tuberculous disease, or to expect that the maximum amount or anything like the maximum amount, of prevention which is attainable with our present means of prevention will ever be reached.

Another objection, which is practically the same as that which has just been considered, is that the compulsory notification of phthisis would interfere with the liberty of the subject to such an extent that it would not be accepted by the people of this country This objection seems to be based upon the supposition that if the notification of phthisis were made compulsory the same action (restrictive measures) would necessarily follow as in the case of the contagious and infectious diseases scheduled under the Act of 1889

I have, however, already pointed out that the action which would follow the compulsory notification of phthisis would necessarily be very different from the action which follows the compulsory notification of the infectious and contagious diseases scheduled under the Act of 1889, since the reasons for notification are entirely different in the two cases—I mean the contagious and infectious diseases scheduled under the Act of 1889 on the one hand and the great majority of cases of phthisis on the other—and in those (dangerous) cases of phthisis in which compulsory removal to a hospital is urgently required I see no reason why the public should merely because of their chronicity, though I admit that their numbers would be a great practical difficulty and that for a time at least one would have to be content with dealing with the worst (most dangerous) cases only, object to such compulsory removal since it would only be practised because the patients were a distinct source of danger to their neighbours and to the community, any more than they object to the compulsory removal of cases of the infectious or contagious diseases scheduled under the Act of 1889 But, as I have just stated, the public do not as yet seem to be prepared to consent to such restrictive measures, though individually I am strongly of opinion that without such restrictive legislation it will be impossible to reduce the prevalence of the disease to anything like the lowest possible attainable limit. Too much weight must not, however, be attached to this admission as an argument against the compulsory notification of the disease, for I submit that the compulsory notification of phthisis would still be of immense benefit even if it did not carry in its train compulsory powers for dealing with (i.e. removing to hospital) those patients whose sanitary surroundings are eminently bad and who are either (*a*) unable or (*b*) unwilling to adopt the necessary preventive measures, though I believe that the benefits which would result from any system of compulsory notification would be considerably lessened if it did not carry with it compulsory powers for dealing with those cases of phthisis which I have termed "dangerous"

The next argument—or rather, series of objections—which has been advanced against the proposal is that the compulsory notification of phthisis would entail great hardships on phthisical patients since it would lead to a large number of them being dismissed from their employments, that phthisical patients who had been dismissed in this way would in future take care not to afford any outward evidence of their malady by the adoption of precautionary measures urged on them in [illegible] of the public, that would consequently, after being once dismissed from employment, avoid consulting another medical practition and that a large amount of harm would therefore resul the disease were scheduled under the list of notifia diseases under the English Act, for the knowledge th notification would ensue would prevent resort to medic advice in the early stages of the disease when its could be best arrested.

I admit that if the premises on which this argument is based are correct and that if the conclusions which are founded on those premises are accepted they form serious and weighty objections to the compulsory notification of the disease But, I ask, are these premises and these conclusions correct? And my answer is that I do not think so It is argued that "the justification for the that phthisis shall be compulsorily notified lies in the fact that the person in question is suffering from a dangerous infectious disorder communicable from person to person." I emphatically protest against, and disagree with, this of stating the fact that phthisis is an infectious disease which may under certain circumstances be communicated from person to person, for it is, I maintain, calculated to give an altogether erroneous conception of the infectiousness of phthisis and of the danger which a healthy unaffected person runs of contracting the disease from being in contact with a person affected with the disease, and it is, therefore, calculated to do harm by unduly alarming the public. In my opinion it would be more correct to say that the justification for the demand that phthisis shall be compulsorily notified is founded on the belief that it (compulsory notification) is necessary and essential in order to reduce the prevalence of the disease to the lowest attainable poin I allow that if the public are taught, without an qualification, to believe that phthisis is a dangerous infectious disorder communicable from person to person loss of employment would be likely to follow the compulsory notification of the disease. But I emphatically dissent from the unqualified statement that "phthisis is a dangerous infectious disease communicable from person to person" I submit that if the public were made thoroughly to realise and to appreciate the fact that a healthy person who lives or works in close contact with a patient suffering from phthisis runs, practically speaking, little or no risk of contracting the disease, provided that certain simple precautionary measures are carried out (notably the disinfection or destruction of the sputum while it is still moist), such loss of employment would be much less likely to occur than has been supposed. The fact that, provided the sputum is destroyed thoroughly disinfected while it is still moist, the r of infection in cases of phthisis is so slight that practical purposes it may be entirely ignored is of par mount importance. It is of the utmost importance that should be brought home to the public. The public must b made to understand (1) that phthisis is not dangerous except through the sputum,[4] (2) that the sputum is easily dealt with (disinfected and destroyed), and (3) that if the sputum is disinfected or destroyed while it is still moist and proper precautions are taken in respect to ventilation and cleanliness there is practically no risk of being in close contact with a patient affected with phthisis.[5] The latter statement is abundantly justified by the statistics of the Brompton Hospital and by the opinion of numerous weighty authorities. These observations show that even in hospitals specially devoted to the treatment of consumption and filled with phthisical patients the physicians, nurses, and attendants do not acquire the disease, provided that proper attention is given to ventilation, cleanliness, and the disinfection of the sputum Cornet states "The consumptive in himself is almost harmless and only becomes harmful through bad habits."

I of course admit that a healthy person should not sleep in the same bed with a patient suffering from phthisis. I admit that if this condition were enforced a certain limited number of phthisical patients would lose their employment.

---

[4] In the present connexion I need not refer to the diarrhœa which results from tuberculous ulceration of the intestine since tuberculous ulceration of the intestine does not occur in the early stages of phthisis and since persons affected with tuberculous ulceration of the intestine whether occurring as a late event in the course of ordinary phthisis or as an early event in the course of generalised (acute) tuberculosis are not in a position to follow their employment.

[5] Except through inhaling particles of sputum coughed into the atmosphere, or through kissing, or using a cup [illegible] taminated with phthisical sputum.

But this is inevitable It cannot be prevented under any circumstances (whether the compulsory notification of the disease is adopted or not) provided that it be granted—and every one, I presume will grant this—that the healthy (unaffected) members of the community have a right to be protected from infection. It must be remembered that the healthy members of the community and healthy employés have, at least, equal rights with the diseased (phthisical) members and diseased (phthisical) employés I therefore maintain that no employer has a right to allow—and the sanitary authorities have no right to permit, if they can prevent it—an employé who is suffering from phthisis to sleep in the same bed with a healthy employé. I further suggest—though this is no doubt a debatable question since the risk that a healthy person runs of being closely associated with a patient suffering from phthisis is a small risk—that no right-minded employer of labour should, if he can prevent it, allow a person who is suffering from phthisis to work in close contact with other healthy employés, unless he (the employer) is satisfied that the proper precautionary measures (for the destruction of the sputum, for ventilation and cleanliness) are carried out, since such preventive measures are in most cases at all events simple and are easily and readily carried out. I maintain that the healthy members of the public—the large majority—have a right to demand that they should be adequately protected against phthisis, just as they have a right to demand that they should be adequately protected against the diseases scheduled under the Act of 1889 notwithstanding the differences as regards chronicity

I conclude, then, that if the public were made clearly to understand that there is little or no risk of a healthy person contracting phthisis from being in close contact with a person affected with phthisis, provided that proper precautions with regard to cleanliness, ventilation and the disinfection of the sputa are carried out, the loss of employment which it is stated would result from compulsory notification would be much less than has been supposed.

But I go further than this and I suggest that the compulsory notification of phthisis instead of being likely to cause the dismissal of phthisical patients from their employments, would on the contrary, be likely to maintain them in their employments. My reasoning is as follows. Up to the present time or until quite recently the public have not realised the fact that phthisis is under certain circumstances an infectious disease—i.e. capable under certain circumstances of being conveyed from the sick to the healthy Consequently phthisical patients have been allowed to work in close contact with healthy persons, and even to sleep in the same beds with healthy persons, without any special precautions being taken. The great advance in public knowledge regarding phthisis which has recently taken place and which is making rapid progress every day has placed the position on a very different footing The public have been now taught to regard phthisis as an infectious disease. But, as I have already pointed out, this statement requires qualification—it is in short, essential that the public should be also taught that there is practically little or no risk of infection provided the proper precautions are taken and that these precautions are simple and easy Consequently it reasonably may be expected that as soon as the public thoroughly realise that there is a risk of the disease being propagated from person to person unless satisfactory precautions (for the destruction or disinfection of the sputum and as regards ventilation and cleanliness) are taken right-minded employers of labour will not allow persons affected with phthisis to be employed along with other healthy persons, and, therefore will dismiss persons who are *suffering from phthisis*, or whom they suspect to be suffering from phthisis from their employment, unless the necessary and simple precautionary measures to prevent infection are taken, and healthy persons will object to be employed in close contact with persons suffering from phthisis or persons whom they suspect to be suffering from phthisis unless such precautions are taken. But if they (the public, the employers of labour and the healthy employés) are made to understand, as they should be made to understand that there is little or no risk from being closely associated with persons suffering from phthisis provided that the necessary and simple preventive measures (for the destruction of the sputum ventilation and cleanliness) are carried out, and if they realise that by a compulsory system of notification every person who is suffering from phthisis will, as soon as he applies for medical advice be carefully instructed with regard to the necessary preventive measures, and that medical men and the sanitary authorities will do their best to see that such preventive measures are carried into effect, they will feel that they have in compulsory notification and the precautionary measures based thereon a protective measure which is of great benefit to them—which is a distinct safeguard to them. In short they will realise that with a system of compulsory notification there is much less risk than there would be without a system of compulsory notification of their being associated with patients suffering from the disease. Consequently it may be reasonably expected I suggest that in the future phthisical patients will run less risk of being dismissed from their employments if a system of compulsory notification is adopted than they would do if a system of compulsory notification were not adopted

Since the foregoing paragraph was written I find that the same opinion has been expressed by Dr Newsholme. He says —

> While writing the above I have heard of the case of a clerk who appears to have been discharged from his post because he was phthisical in connexion with the recent publicity given to the dangers arising from the sputa of such patients. If the admirable propagandism of the Association for the Prevention of Tuberculosis is to continue (and we all hope that it will) a certain amount of alarm among those imperfectly informed is inevitable In all probability nothing would be more successful in removing this unreasonable fear (unreasonable when proper precautions are taken) than the knowledge that cases of phthisis are notified to the medical officer of health who has official charge of any necessary precautionary measures.

But even granting that loss of employment did occur in a certain proportion of cases, are we justified for this reason in concluding that the compulsory notification of the disease should not be adopted? I do not think so. A certain *amount of hardship must necessarily result if the prevalence* of phthisis and other forms of tuberculous disease is to be reduced to the lowest attainable limit. The few must unfortunately suffer for the many Year by year as the disease would become eliminated from the population, the few would become fewer and fewer If I am right in thinking that it is impossible to reduce the prevalence of phthisis to anything like the lowest possible attainable limit without a system of compulsory notification, if compulsory notification would afford as I hold it would undoubtedly do, valuable assistance in the prevention of phthisis and is essential and if our preventive measures are to be thorough and effectual we are surely justified in disregarding however much we may deplore it, the hardship which would be enjoined upon the few The benefit to be gained by the many in my opinion far outweighs the hardship (loss of employment) to the few

Let me next consider whether the compulsory notification of phthisis would have the disastrous effects which it is stated it would have in preventing patients suffering from early phthisis taking medical advice and the necessary measures for the cure of their disease. In considering this question it seems to me essential in the first place to determine whether a healthy person does or does not run a risk of contracting the disease from being closely associated—as for example in a workshop office, or shop—with a patient suffering from phthisis That there is some risk (though I believe in the case of perfectly healthy persons it is comparatively speaking a small risk) unless the proper preventive measures (for the destruction of the sputum satisfactory ventilation, and cleanliness) are taken, everyone will, I suppose, allow That this risk is greatly diminished and is, practically speaking abolished if such precautions are taken everyone or almost every one will I suppose, also allow Further it must be admitted that a compulsory system of notification such as I have suggested would in some degree diminish the risk to the healthy employés since it would, to some extent at all events, ensure that the necessary preventive measures were carried out. Again it must be allowed that the healthy employés have a right to demand either that they should not be employed alongside phthisical patients or that the phthisical patients should be obliged to take the necessary and simple precautions to prevent their being dangerous to their neighbours. I have, further suggested that if the public are made to understand that there is practically no risk of associating[*] with phthisical patients provided that certain simple and easily carried out precautions are adopted, in the future phthisical patients will if they take such precautions and if a compulsory system of notification be adopted, be less liable to be dismissed from their employment than if they did not take such precautions and if a compulsory system of notification were not adopted

---

[*] I exclude sleeping with phthisical patients for this as has been already pointed out, is attended with some risk.

Now if these propositions are granted, then it must I think, be allowed that the disastrous results which have been suggested as the results of compulsory notification—viz , concealing the nature of the complaint, refusing to adopt obvious precautionary measures and to take advice at the stage when the disease is curable, and the extension of infection to others—will not follow But even granting, for the sake of argument, that considerable numbers of phthisical patients were for the reasons suggested dismissed from their employment, is there sufficient reason to suppose, as has been argued, that they would in order to obtain situations elsewhere refuse to place themselves—or rather, I would say, to continue—under medical treatment in the early and curable stage of the disease? Such a result might perhaps have been expected to follow a few years ago But would it follow at the present day? I do not think it would be likely to do so in any large proportion of cases of early phthisis, provided that the patients could obtain medical advice and could manage to carry out the appropriate treatment. A few years ago phthisis was popularly regarded as an incurable disease We now know that, provided that the right means of treatment are employed at a sufficiently early stage of the case, it is a curable disease in a considerable proportion of cases And if the public are only made thoroughly to realise this fact it is surely reasonable to suppose that even those phthisical patients who should happen to be dismissed from their employment would, in most instances at all events, endeavour by every means in their power to adopt the necessary means to become cured

In connexion with the compulsory notification of phthisis I have advocated the formation of sanatoriums for the treatment of cases of early and curable phthisis , and what more appropriate cases for admission to such sanatoriums than patients affected with early phthisis who have been dismissed from their employment? If a determined effort is to be made to stamp out phthisis a certain amount of sanatorium accommodation must be provided. This will, of course, involve a large expenditure, but I have already insisted upon the fact that it is hopeless to attempt to deal with the disease in a thorough and effective manner without a very large expenditure of money I do not mean to suggest that sufficient sanatorium and hospital accommodation must be immediately provided for the reception and treatment of every case of phthisis and for the retention of every early case of phthisis until the disease is cured or until the tubercle bacilli have disappeared from the sputum. This seems to me to be quite impracticable But I do think that if a determined effort is to be made to reduce the prevalence of the disease to the lowest attainable limit the charitable public and the Poor law authorities ought to provide a certain amount of sanatorium accommodation for the treatment of cases of early and curable phthisis, and the sanitary authorities ought to provide a certain amount of hospital accommodation for the more "dangerous" cases of the disease

I would further point out that it is not essential that the early cases should remain in sanatoriums for prolonged periods of time—i.e , until the disease is completely cured or until the tubercle bacilli have disappeared from the sputum—though this would, of course, be advisable and eminently desirable if it could be managed Even if the early cases of phthisis could be placed in sanatoriums for a limited period—a few weeks only—until the patients were instructed and drilled in the measures which it is advisable and necessary to take for the treatment of the disease and for the prevention of the extension of the disease to others (i.e , for the destruction and disinfection of the sputum), the beneficial effects both to the patients themselves and to the community at large would be enormous After his discharge from a sanatorium the patient who had been thoroughly taught to carry out the necessary precautionary measures might safely be employed alongside healthy persons and be allowed to follow his ordinary employment, so far at least as the welfare of his fellow and healthy employés was concerned

In short, for the reasons already given I do not anticipate that a compulsory system of notification specially adapted to phthisis would have the disastrous results, either as regards loss of employment or as regards refusal to continue the necessary medical treatment, which have been suggested Even if it is admitted that a certain proportion of phthisical patients would probably lose their employment, I believe that if the necessary hospital and sanatorium accommodation were provided they would, in most instances at all events, willingly agree to continue under medical treatment and to do everything in their power to get cured of their disease. This would not, of course, meet the difficulty of providing for the wives and families of those phthisical patients who were thrown out of employment while they—the bread winners—were undergoing treatment in a sanatorium or hospital This is, in my judgment, one of the greatest practical difficulties connected with the subject But it is absolutely impossible to prevent some hardships if the disease is to be dealt with thoroughly and satisfactorily It would be the duty of the Poor law authorities and of the charitable public to provide for the maintenance of the wives and families of such phthisical patients

Lastly, it is argued that the compulsory notification of phthisis would retard the very object which its advocates have in view, since it would alienate the public in regard to the measures of prevention which cannot succeed unless they have the support of public opinion This is simply, it seems to me, another way of stating that the objections to the compulsory notification of phthisis are greater than the advantages which it would confer The whole object of this communication has been to show that, under a system of compulsory notification specially adapted to phthisis, such need not, and in fact would not, be the case. I believe that if the public once thoroughly realised the *enormous* benefits which they would derive from reducing the prevalence of phthisis to the lowest possible attainable limit , if they once became convinced that without the compulsory notification of the disease it was impossible to attain this end , that the compulsory notification of phthisis was essential in order to attain this end , and that it was possible to introduce a system of compulsory notification which would work effectively and smoothly in practice , in short, if the public were once convinced that the advantages to be gained by the compulsory notification of the disease were greater than the disadvantages, hardships, &c , which it would entail, then, instead of being alienated by the proposal they would willingly submit to the proposal and would agree, and in fact demand, that it should be put in operation The medical profession, who are able to appreciate the subject in all its bearings and whose willing a active coöperation is essential for the success of any schem of compulsory notification for phthisis, must be first convinced on these points , and it is with the object of trying t convince the profession, and through them the public, that the advantages of a *compulsory system of notification specially adapted to phthisis* are far greater than are the disadvantages, that these lectures have been written and are now published

THE
SIMULATION OF ACUTE PERITONITIS BY PLEURO-PNEUMONIC DISEASES

BY H. L BARNARD, M S LOND , F R C S ENG ,
ASSISTANT SURGEON TO THE LONDON HOSPITAL AND TO THE METROPOLITAN HOSPITAL

THIS paper deals with a class of cases in which it is n easy to mistake thoracic for abdominal disease. This dec tive likeness of two diseases is not of purely theoreti interest, for a mistaken diagnosis is often followed in such case by an unnecessary operation. This condition, whil well known to the older physicians, has dropped out of notic in recent years, and that is some excuse for this paper

CASE 1 *Right diaphragmatic pleurisy and pneumonia with marked abdominal signs, simulating appendicitis with peritonitis* – This case I owe to the kindness of Dr P Kidd A little girl, aged 11 years was admitted to the medical wards of the London Hospital in 1895 complaining of pain in the head, but especially in the abdomen Three days before admission she had severe pain down the right side of the abdomen and vomited bilious fluid several times. When she was first seen at the hospital her abdomen was rigid and especially tender in the right iliac fossa. Her bowels had not been opened for three days and her tongue was brown and dry Her pulse was 104 full and not easily compressed and her temperature was 103° F The thoracic signs which at no time were very marked, were almost absent on admission, she was, however breathing about 40 to the minute and cut her respirations short because they hurt her in a manner characteristic of pleurisy She had moreover tenderness along the attachment of the diaphragm and the veins were dilated there By the fourth day after admission there were obscure signs at the right base of some pneumonia, the breath sounds were a little diminished, and there were a *few moist râles, but these were also heard at the left* base. Her temperature which had remained at about 103° fell by crisis to normal on the fourth day, but soon became irregular and for four or five weeks it frequently reached 102° During this time the signs of pneumonia and diaphragmatic pleurisy became more distinct and at last left no doubt as to her condition but had she been admitted to a surgical instead of a medical ward, and at the present time when so many cases of appendicitis are submitted to early operation instead of seven years ago I cannot help thinking that her abdomen would probably have been explored.

CASE 2. *Pleuro-pneumonia of the right base acute abdominal pain and vomiting no lung signs herpes labialis empyema recovery*—This case I owe to the kindness of Mr H P Dean and Dr G Schorstein. A little boy aged 10 years, was admitted to the London Hospital in 1899 as suffering from acute peritonitis after an injury Two days before admission he had received a blow in the lower part of the chest or in the upper part of the abdomen On the following day the day before admission, he was seized with severe pain in the abdomen, chiefly in the upper part, and he vomited twice. On admission, his abdomen was found to be somewhat distended tender and rigid all over but especially so in the epigastric region. His bowels had been constipated since the pain commenced and an enema only gave a small result. He lay with both legs drawn up. His temperature was 99 5° F on admission but it rose to 103° the same evening His pulse ranged from 130 to 140 but was of good volume and strength His respirations were 44 per minute and catchy The examination of the thorax gave absolutely negative results Soon after admission he developed herpes labialis and was transferred next day to the medical side No signs had yet appeared in the thorax but on the following day there was undoubted consolidation at the right base. The temperature fell by crisis on the ninth day of the disease but seven days later it rose again and became irregular and empyema developed on the right side. This was opened and drained and he then made a good recovery

CASE 3. *Double basal pneumonia with right diaphragmatic pleurisy in a girl the subject of a gastric ulcer acute epigastric pain with collapse laparotomy death*—This case is certainly the most perplexing one that I have yet heard of I am indebted for it to Mr F S. Eve A girl aged 17 years, had been attending the out-patient department of the London Hospital for some months for marked anæmia and gastric ulcer She had had once before a similar attack to the one which I am about to describe. One morning in 1899 she started for work as usual and on her way was seized in the street with violent epigastric pain and vomiting She was brought to the hospital at once in a state of collapse. Her pulse was 120 and very thready and her temperature was 104 5° F Her abdomen was rigid, motionless very tender and distended, and these signs were most marked in the epigastric region. She was admitted to the surgical wards as a case of ruptured gastric ulcer and within two hours Mr Eve opened her abdomen He explored the anterior and posterior surfaces of the stomach the greater and lesser curvatures but found no trace of gastric ulcer nor was there any peritonitis. Unfortunately ether was the anæsthetic given. Misfortunes followed fast Her cough became so violent that a coil of intestine and some omentum escaped between the stitches and had to be washed and returned and the abdomen again sewn up. On the second day after admission it was clear that she had right basal pneumonia but her temperature had fallen to 101° On the third day it rose again to 104° and signs of consolidation appeared at the left base and she died on the fifth day from the commencement of the attack. At the post mortem examination double basal pneumonia and right diaphragmatic pleurisy were found and in the stomach was a shallow ulcer of the size of a sixpenny piece which was not even near perforation. There was no peritonitis. I think that all will admit that this was an impossible case to diagnose correctly Looking back at the case the only point which should have aroused suspicion was the temperature of 104 5° No record of the frequency of respiration was kept

CASE 4 *A case of pyopneumothorax of the left base simulating appendicular peritonitis or left subphrenic abscess of gastric origin.*—A male Hebrew aged 34 years was admitted to the London Hospital under a medical colleague for colic and peritonitis in 1901. I was asked to give a surgical opinion on his abdominal condition. He had not been well for a year suffering chiefly from pain and wind in the stomach after food but without vomiting For several weeks he had also had pain in the left lower and back part of his chest with a bad cough and night sweats and wasting He had been constipated for 12 days. When I saw him his temperature was 101° F his pulse was about 100 and fairly strong and his respirations were 38, his nares being vigorously dilated at each inspiration He was a little icteric but not really jaundiced. His abdomen was rigid and very tender all over but I could make out no local dulness or resistance and the abdominal wall relaxed between each respiration. The base of the left lung behind was dull on percussion. Vocal resonance and tactile vocal fremitus were diminished. Such breath sounds as could be heard were of a somewhat tubular character The house physician thought that the right iliac fossa was more rigid and resistant than the rest of the abdomen. The medical registrar was of opinion that the signs indicated left subphrenic abscess due to a perforated gastric ulcer but the stomach resonance was normal and the spleen was not displaced. My medical colleague agreed with me that the signs appeared to indicate trouble above the diaphragm and arising from the lower lobe of the left lung Ten days later it was clear that he had pyopneumothorax at the left base, probably arising from a tuberculous focus in the apex of his left lower lobe. A rib was accordingly resected and his temperature fell to normal. He put on flesh and lost all pain but a sinus persisted when he left the hospital.

CASE 5 *A case of pyopneumothorax of the right base simulating appendicular peritonitis*—On Sept. 12th, 1901 I was called late one evening to see a man in the wards of the London Hospital who was said by my house surgeon to be suffering from appendicitis and general peritonitis." Two days before admission the patient was running for a train on his way to work in the morning when he was seized with severe pain in the right iliac fossa. He gave up work at 1 P M on the same day and took to his bed Next day his bowels were well opened by a pill and castor oil. He had no vomiting He had never been seriously ill before. When I saw him in the wards it was clear that he was seriously ill and in great pain His temperature was 100° F his pulse was 80 his respirations were 43, and his tongue was furred and dry His abdomen was hard rigid and tender all over but perhaps a little more so in the right iliac fossa. It relaxed however between the respirations for a second and became soft and there was no marked distension or localised dulness or resistance. The heart was normal and the examination of the lungs showed nothing but a little bronchitis and emphysema. I refused to operate because whilst the abdominal signs appeared to me at least doubtful the respirations—43 a minute with a pulse of only 80—appeared to indicate that the lungs were the source of the trouble. The thing however which really decided me not to operate was that I did not think that he could safely take an anæsthetic. I carefully examined him again on the next day with a medical colleague. The abdominal signs had disappeared almost entirely and dulness at the right base with diminished breath sounds and tactile vocal fremitus the presence of a pleural rub, and the absence of tubular breathing left no doubt that he had right basal pleurisy Eight days later the signs at the right base had much increased and pus was found by an exploring needle. A rib was resected and 24 ounces of pus with air were evacuated. The condition was then found to be one of pyopneumothorax I saw him once again in February 1902. He had been attending the out-patient department for a sinus left by the empyema. An energetic dresser had syringed out his cavity with some antiseptic and had nearly choked him by the passage of the fluid through the orifice in the lung into the trachea.

CASE 6. *Traumatic left pleurisy with abdominal signs laparotomy*—A labourer aged 38 years was admitted to the London Hospital under my care in February, 1901. giving the following history He was assisting to unload deal planks from a barge when one of the planks swung round suddenly whilst hanging from the crane and struck him violently over the lower left ribs, precipitating him 12 feet into the barge where he alighted on the back of his head. He was slightly concussed and had a scalp wound in the occipital region. He soon recovered from the shock of the fall and the only sign of the injury which could be made out was a fracture of two of his left lower ribs, probably the ninth and tenth, but he was so muscular a man and the part was so tender that the exact ribs broken could not be determined. Within 12 hours of admission a pleuritic rub was heard in the region of the broken ribs. On the next day acute abdominal signs appeared. He complained of violent abdominal pain which was worse down the left side of the abdomen. His abdomen was rigid all over but especially in the left hypochondrium and lumbar regions, the abdominal wall, however, still moved on respiration. Ill-defined dulness was found down the left side and this was thought to be due to blood in the peritoneum. He vomited continuously and the vomitus soon became bilious. His bowels had not been opened since he was admitted and an enema of one and a half pints of soap-and water was given. This was retained. Retention of urine which had been present since admission persisted. His temperature was 99° F. and his pulse was 75 and of good volume. A diagnosis of laceration of the spleen with recurrent hæmorrhage was made, and laparotomy was decided upon. I must admit that this diagnosis was largely due to the fact that within a fortnight a very similar case had been admitted to the same ward and did not develop any marked abdominal signs until the fifth day when the patient was to have left the hospital. On that day he collapsed and his abdomen became distended and much free fluid was discovered. Laparotomy was performed and the spleen was found to be torn nearly in two. He died from hæmorrhage on the table whilst the clots were being displaced to find the pedicle. The abdomen in the present case was opened in the left linea semilunaris and the abdominal contents were found to be absolutely normal. The dulness was explained by the enormous muscular development of the abdominal wall, which was so great that the recti and lateral abdominal masses projected into the peritoneum as rounded masses, which were at first thought to be hæmatomata. The great muscular development of the abdominal wall was apparently due to the man being by trade a deal runner. Some idea of the spasm may be gained by the fact that strand after strand of ordinary silkworm gut snapped without drawing the edges of the incision together, and finally the stoutest silk had to be employed and the anæsthetic vigorously pushed before the abdominal wound was closed. The wound healed by first intention and the patient made an uninterrupted recovery.

Andral[1] appears to have recognised this condition clearly in 1836 and in his book narrates several typical cases. Watson,[2] in his admirable text-book of medicine, quotes Andral and refers to cases of his own in which pleurisy at the right base simulated hepatitis, but he does not appear to have recognised the possibility of confusing diaphragmatic pleurisy with acute peritonitis. Fagge knew the condition well. In his text-book he says: "In exceptional cases the pain is referred to the terminal branches of the intercostal nerves, to the hypochondrium so as to lead to a mistaken diagnosis of hepatitis, to the loins, so that the case has been called one of lumbago, or to the neighbourhood of the umbilicus, so that peritonitis has been suspected", and in a note he adds: "I have myself had a patient whose sole complaint was of pain in the crista ilii. I feel sure that if it had not happened that a short time before my attention had been specially directed to this question I should have failed to discover that he had pleurisy, although on applying my stethoscope I at once heard a rub.—C. H. F."[3] Modern medical writers for the most part are vague in their reference to this class of case and many do not even refer to them at all. The condition is altogether unknown to surgeons if we judge from their text books and this is all the more unfortunate as it is they who will open the abdomen of the pleuritic patient should they be ignorant of this condition after they have caused ether to be administered. My excuse for this paper is to call attention to a pitfall in surgery into which, as may be seen here, I have fallen myself.[4]

The thoracic diseases which can give rise to such severe abdominal signs as [illegible] in the lower part of [illegible] or the adjacent p[illegible] of my cases were [illegible] the lung, involvin[illegible] which apparently [illegible] lower lobe rupture[illegible]y, producing pneumothorax. One case was most interesting in that the pleurisy was traumatic, due to a localised injury and associated with broken ribs, it was recognised and yet the abdomen was opened, so definite were the abdominal signs.

The abdominal signs and symptoms which may arise in such conditions are conveniently divided into parietal and visceral.

Parietal.—The abdominal wall is acutely tender and painful. The tenderness often extends over the whole abdomen, but in some cases it is unilateral, it may be present only above or below or be more intense in these situations. It will readily be seen that such acute abdominal pain and hyperæsthesia in the right hypochondrium may be mistaken for hepatic and biliary diseases, whilst in the right iliac region an appendicitis would at once suggest itself and in the epigastrium a perforated gastric ulcer. The abdominal muscles are, moreover, in spasm so that the abdominal wall is board like and hard. So great is this spasm that the deepest anæsthesia is necessary to relax it and the pupils will be widely dilated before the abdomen becomes soft. This has practical application, for if the intestines are allowed to escape they will be returned to the abdomen with the greatest difficulty and the surgeon will find that the stoutest silk alone will stand the strain necessary to close the wound. The respiration is of the costal type, but it will be found on placing the hand upon the abdominal wall that this relaxes for a moment at each inspiration, and this is an important diagnostic sign. Writers on diaphragmatic pleurisy insist on the importance of unilateral exaggeration of costal respiration on the side of the chest affected.

Visceral.—The visceral signs are distributed along the whole length of the alimentary canal. Gastric disturbance leads to nausea, hiccough, and vomiting which may be urgent and become bilious. The intestines are apparently more or less paralysed, so that the abdomen becomes distended, and this, with the tenderness and spasm of the abdominal wall already referred to, produces a most deceptive resemblance to peritonitis. Constipation is nearly always present and enemas may be retained, so that apparently the rectum has lost its irritability. Even the profound vascular changes which we are in the habit of associating with severe lesion in the splanchnic area are frequently present, at least at the onset of the attack, although it must be admitted that they do not often persist or become more severe as the disease develops.

The patient is often collapsed at the onset of the pain. The extremities are cold and beads of sweat may break out on the forehead, whilst the features are pale and pinched, but in none of my cases did I see the rings round the eyes or the dry shrivelled tongue which one associates with general suppurative peritonitis.

DIAGNOSIS.

The diagnosis is nearly always easy if suspicion is aroused and the surgeon is aware of this deceptive condition. The chief points to be observed are the rapidity of the respiration, often 40 a minute or more, which is out of all proportion to the pulse rate, which is seldom so frequent as 100 a minute and is not weak or wiry. The respirations will often exhibit the curious catch at the top of inspiration which is characteristic of pleurisy. The abdominal tenderness is, moreover, found to be chiefly superficial and firm deep pressure with the flat hand may be permitted. It will then be found that the abdominal wall becomes soft for a moment at each inspiration which is not the case in acute peritonitis. The absence of rings round the eyes and a temperature of about 103° should also make one hesitate to diagnose a serious and general peritoneal infection. When once a suspicion has dawned on the mind of the surgeon the patient is comparatively safe, for an examination of the suspected side of the thorax will reveal some dulness or friction sound or some excess of costal movement on that side over the other which will lead him to pause and perhaps to consult his medical colleague, but it must be frankly admitted that direct thoracic signs are often almost entirely lacking for 24 hours or more.

The great danger, after all, appears to arise from an auto-suggestion by the patient's surroundings and the circumstances under which he is first seen. The surgeon is summoned by his house surgeon, perhaps in the dead of night, to see a case of ' acute peritonitis probably of appendix or gastric ulcer origin. He goes to his well known ward where he has seen series of cases of every phase of abdominal disease but seldom or never pleurisy or pneumonia. There he finds a patient suffering from acute abdominal pain perhaps vomiting and the house surgeon tells him that the patient has retained an enema. The pain the patient is in and perhaps his cries when he is being examined, disturbing the whole ward as they do at night, prevent a complete examination. It may be that the surgeon is not quite satisfied that the signs undoubtedly indicate general peritonitis but his clinical experience at once reminds him how vague the signs of general peritonitis may be of the case of ruptured liver or spleen in which the signs were so vague for three or four days that operation was postponed until too late or of that case of ruptured gut which for two days was supposed to be abdominal contusions. In such circumstances it is really not surprising that patients exhibiting the signs which I have mentioned are sometimes operated on This is an accident always to be deplored, for very frequently ether is administered and this adds bronchitis to the pre-existing lung condition, whilst an extensive abdominal incision seriously hinders coughing The only guard against such deplorable accidents is to recognise the possibility of their occurrence and that is my excuse for this paper and the record of those cases.

[4] Since this paper was read at the Clinical Society on April 11th, 1902, a paper has appeared on the Simulation of Appendicitis by Acute Intra thoracic Disease by Dr. Maurice H. Richardson, Boston Medical and Surgical Journal, April 17th, 1902.

PATHOLOGY

The pathology is one of referred pain and divides itself into three heads

1. *Irritation in continuity* of the lower six dorsal nerves will explain the hyperæsthesia and spasm of the abdominal wall. These intercostal nerves supply the diaphragm and lower part of the pleura and here their branches if not their trunks, will be irritated by an acute inflammatory process. The terminations of the seventh to the eleventh dorsal nerves pass to the abdominal wall and supply the skin and muscles there. If the seventh eighth and ninth nerves are chiefly affected the acute epigastric tenderness and spasm will closely simulate a perforated gastric ulcer or if chiefly hypochondriac and on the right side hepatitis or gall bladder trouble. When the tenth dorsal nerve is mainly affected the pain is referred to the umbilicus as it is in so many abdominal complaints, whilst the area of the tenth and eleventh dorsal nerves on the right side is that in which the signs of an acute appendicitis develop. Moreover the presence of tenderness and spasm on the left side in the tenth and eleventh dorsal areas does not exclude appendicitis, for in the early stage of this affection the pain may be referred to that side It is interesting to note that three of my six cases terminated in suppuration. This seems to indicate that the inflammation in order to produce such abdominal signs must be severe enough to penetrate to the nerve trunks themselves and to produce actual neuritis

2. *Referred visceral pain* has been most exhaustively studied by my colleague Dr Henry Head[*] and it will explain referred abdominal pain from lung disease without pleurisy The seventh eighth and ninth dorsal rami communicantes are those which supply the lungs When broncho-pneumonia, phthisis or bronchitis but not lobar pneumonia supervene, even without pleurisy impulses may pass up to the posterior root ganglia of these nerves and there produce such changes that normal impulses passing through these ganglia from the terminal branches of the nerves in the epigastrium and upper abdominal wall are exalted into painful impressions. The spasm follows in a reflex manner from the pain. Dr Head tells me that he has seen such cases but none of those related here are explicable on this pathology

3. *Of the pathology of the visceral signs* to which I have referred gastric, intestinal rectal, and vascular we know very little Perhaps they are the result of a reflex in the reverse direction to that to which I have just alluded to that irritation of the six lower intercostal nerves by a pleurisy produces disturbance in the distribution of the three splanchnic nerves which are derived from the same level of the spinal cord. On the other hand it may be due to irritation of these nerves in continuity as they lie beneath the pleura or pass through the diaphragm to the great sympathetic plexuses and ganglia of the abdomen

Welbeck-street W

A CASE OF RECOVERY FROM MEMBRANOUS GASTRITIS

BY OTTO GRÜNBAUM M B CANTAB M R.C P LOND

MEMBRANOUS gastritis is a condition characterised by an exudation from the epithelial lining of the stomach leading to the formation of a false membrane over the whole or part of that viscus. The symptoms of the disease are extremely variable. Thirst is often distressing occasionally vomiting is uncontrollable and pain in the stomach may be considerable, but cases have been recorded in which no symptoms have existed The pathognomonic sign is the vomiting of a cast of the stomach or shreds of croupous membrane, but owing to the rarity of the presence of this sign along with the fact that this form of gastritis usually occurs as secondary to a grave disease which averts attention from the gastric symptoms, the condition is not frequently diagnosed during life. In membranous gastritis the cast consists of fibrin and blood cells only, while in phlegmonous inflammation of the stomach the necrosed mucosa is shed This difference is not strictly adhered to in the literature on the subject.

As to the rarity of the disease authorities agree but they differ in their experiences as to the most frequent causes Rokitansky[1] states Croupy inflammation of the stomach never occurs as a primary and substantive affection except in the shape of delicate flocculent exudations in the aphthous processes of children but always and then rarely as a sequela or degeneration of exanthematic processes, in variola, in typhus, in the absorption of pus into the circulation and particularly in puerperal inflammation of the uterine veins Delafield[2] saw a man aged 46 years suffering from this disease and termed the condition idiopathic because no cause was assignable This author recognises that membranous gastritis is usually secondary to typhus fever pyæmia puerperal fever cholera, dysentery and irritating poisons Von Ziemssen[3] suggests that the condition may arise from the membrane in diphtheria spreading down the œsophagus into the stomach while Ziegler[4] writes that croupous and diphtheric inflammations of the stomach are rare They occur most frequently in typhus fever cholera measles scarlet fever small pox, pulmonary tuberculosis and pyæmia In diphtheria, on the other hand they are extremely rare Wilks,[5] Fox,[6] Kundrat,[7] Goodhart[8] Rotch[9] and several others describe the condition but add little to the above summaries. Recklinghausen[10] saw one case complicating gangrenous pneumonia. Goodhart and Still record that they have seen membrane scattered over the surface of the stomach mostly on the top of the rugæ and accompanied by intense congestion of the mucous membrane in a case of severe broncho pneumonia where there was no evidence of diphtheria. The condition was associated with membranous colitis. Osler[11] found an extensive area of croupous inflammation represented by a thick adherent greyish white exudate covering an area 12 by 8 centimetres in one of his series of 100 cases which died from pneumonia Quite recently Foulerton[12] described a case of membranous gastritis from which he was able to isolate pneumococci. Bizzozero[13] saw two cases during the epidemic of diphtheria at Milan in 1875. The presence of the membrane in the stomach was not suspected during life and caused surprise at the necropsy Six cases of the disease are described by Smirnow[14] osis of the theria, because in that number only two of the gastric mucous membrane evident, prior to the discovery of the Klebs-Löffler bacillus necrosis considered a *sine quâ non* of the diphtheritic process and the absence of necrosis prevented the condition being termed diphtheritic. Talfourd Jones[15] saw a case of exudative gastritis in 1862, his patient was a rachitic child who developed a membrane in its stomach so similar to that which normally appears in the throat in diphtheria that the diagnosis of gastric diphtheria was made. Wollstein[16] reports with great detail and many references two cases, in neither of which any evidence of diphtheria bacilli in the membrane was obtainable. One of the cases was a child suffering from advanced pulmonary tuberculosis, while the other had a false membrane on the inner side of the thyroid cartilage, micrococci were found in the membranes, but no Klebs-Löffler bacilli. The only case so far recorded in which a complete cast of the stomach was vomited is that by J Thomson.[17] The diagnosis of acute pulmonary tuberculosis was confirmed at the necropsy and no evidence of other disease was found. Two cases of undoubted diphtheritic gastritis came under the care of T Leary[18], in one there was membrane in the throat and in the other upon the conjunctiva. From the stomach of the former the bacillus of diphtheria was isolated. Willett[19] recorded a case of diphtheritic membranous gastritis in a child, one and a half years old, who had died from pharyngeal diphtheria. No membrane was found in the œsophagus nor did the exudation extend beyond the pylorus. W S. Fenwick[20] described a case of diphtheria of the stomach in a child three years of age, there was no pharyngeal membrane but "the respiratory tract was lined by diphtheritic membrane from the larynx to the finest ramifications of the bronchial tubes The lower lobe of the left lung was solid from broncho-pneumonia" This membrane was found to swarm with micrococci but no diphtheria bacilli were found. This author points out that the vomit ejected by his patient did not contain hydrochloric acid and Rolleston suggests that the rarity of a gastric false membrane may be due to the solvent action of the gastric secretion.

That it is rare to find a false membrane in the stomach sven when it exists on many other mucous surfaces is well llustrated by the papers of Villy and of Cary and Lyon 'illy[21] examined the gastric mucosa of a large number of patients who died from diphtheria after having had well-marked gastric symptoms The mucous membrane was often invaded by leucocytes and hyperæmic, but in no case lid he find a definite false membrane Cary and Lyon[22] eview the literature of pseudo-membranous inflammation of he mucous membrane caused by the pneumococcus and they nd only one case in which the membrane was seen in the omach. Without criticising the probable accuracy of the agnosis in the above cases they may be classified. 19 cases recorded—eight are ascribed to diphtheria, four to umonia, and two as sequelæ to pulmonary tuberculosis annot help thinking that the cases of membranous gas s which are stated to have followed variola, pyæmia, &c., phlegmonous rather than pseudo-membranous gastritis e patient whose case I am about to describe was a hy looking girl aged three years of a rachitic type. father was consumptive but no further history of the e was obtainable. She had been rickety since she was nths old and was subject to the complaints which pany that disorder Her present illness commenced . 8th, 1902, when the child was irritable and gave her s the impression that she was sickening for some , prior to this she had had a cold for a week. midnight she awoke and complained of a sharp pain ft ear, passing down the neck on the same side and slight stomach ache. Judging from the spells of pain in the head seemed to become more intense ree times during the hour, between midnight and patient vomited four times without, as far as one

became fretful, and four hours la seemed to be wel During t the ear returned, accompanied by vomiting upon her left side, she was sensible and w being disturbed. Both cheeks were flushed slight tenderness over the left mastoid re sufficient to prevent the child from lying on tha was no nystagmus, strabismus, or paralysis of a

In regard to the respiratory system a detailed of the lungs did not reveal any signs of diseas dition of the circulatory system was as follows beat of the heart was behind the fifth rib one inch internal to the nipple line. The heart w rapidly (128 per minute) but the sounds were cle not suggest any cardiac lesion. The pulse was normal volume, and about 100 mm. Hg pressu temperature was 97 8° F The abdomen was rathe of a rachitic type There was no tenderness or res any part. The spleen could not be felt below th margin nor did percussion lead to the conclusi there was any enlargement of that organ The li of good colour and the tongue was moist and but evenly coated. The breath was slightly foul tonsils and fauces were hyperæmic but no tr a membrane was visible in any part of the The vomit consisted of glairy mucus, free from bl blood. The bowels were slightly costive but with exception the motions were normal. In regard to nervous system the knee jerks could not be obtaine either side Although all the superficial and deep refl were examined no other alteration from the normal found. The urine contained a trace of albumin. The bl was examined on Feb. 10th with the following results cells, 4,480,000, and white cells, 8700 per cubic millimet A differential count showed polymorphonuclear cells, 43 per cent., lymphocytes, 48 5 per cent., mononuclear cel (large), 7 9 per cent., and eosinophile cells, 0 5 per cent.

The child complained of great thirst and since vomitin followed even small doses of water by the mouth recta feeding was adopted. On Feb 10th the temperature and pulse remained unaltered. Vomiting occurred repeatedly during the day but the thirst seemed to have been relieved by the rectal injections. In the evening the child again complained bitterly of thirst and was given a few teaspoonfuls of water, shortly after which she cried out with gastric pain and then vomited a piece of membrane, the nature of which will be described later Occasional vomiting continued during the night, accompanied by slight abdominal pain. About 3.30 on the following afternoon, after considerable pain and retching, another piece of membrane was vomited and this along with the former piece seemed to be a complete cast of the stomach The vomiting from this time onward became less frequent, while the condition in other respects remained unaltered. On the 12th with a pulse of 128 and a temperature varying between 97° and 98° F, the patient gave the impression of improving, the tongue being slightly cleaner and the vomiting less frequent. Knee jerks could not be obtained On Feb 14th the pulse was 132 and the temperature was 97 4° The patient slept well during the night but was drowsy in the morning A trace of albumin was present in the urine During the day the child expressed a desire for food On the 16th the pulse was 116 The child had n vomited for 24 hours The heart sounds were weaker a the rhythm rather embryonic. The desire for food was mo marked. On the 17th the pulse was 112 but very weal One ounce of peptonised milk mixed with three times tha quantity of water was given by the mouth and was retained. The patient was improving on the 18th. Milk and beef-juice were digested. From this time onwards the patient steadily improved and *pari passu* with larger quantities of food being taken by the mouth the rectal injections were diminished in volume and frequency The right knee-jerk returned on March 6th and the left on the day following The child has been perfectly well for several months.

Diagnosis—That the case was one of membranous gastritis was placed beyond doubt by the shape and nature of the cast vomited. The cause of the exudation had to be considered The temperature was subnormal, the pulse was rapid, there was slight albuminuria accompanied by the loss of knee-jerks, and a normal number of white cells in the blood. These are all compatible with diphtheria. A swab of the back of the throat was taken on Feb 10th but no

of the Association of American Physicians, 1901, suspicious bacilli were found either in a stained film or by culture on blood serum. I regret that no cultures or inoculations were made from the vomited membrane. Microscopically I failed to find in it any bacilli which resembled Klebs-Löffler bacilli. In toxæmia of diphtheritic origin it is not rare for the heart's action to be altered in rate and rhythm without the temperature of the body being greatly elevated. The temporary albuminuria and loss of knee-jerks make one doubt whether croupous gastritis would have been the correct diagnosis. The subnormal temperature along with an absence of leucocytosis both make it improbable that the membrane was of pneumonic origin. The examination of the blood did not add to the data upon which diagnosis was based. Although a marked leucocytosis as a rule accompanies diphtheria it is not invariably the case. The differential count of the white cells is not far from normal; the child was three and a half years old, at which age normally the polymorphonuclear and mononuclear elements of the blood are present in equal numbers. There is a tendency in rachitis, as in all conditions of malnutrition, for the lymphocytes to be relatively increased and this may have been responsible for the high percentage of mononuclear cells. It is scarcely necessary to add that full investigation as to the possibility of the gastritis being due to an irritant introduced through the mouth was made, with a negative result. The piece of membrane vomited on Feb. 10th was of a shape and size that suggested a cast of the greater part of the stomach, including the cardiac opening; the pyloric end was missing but the tissue ejected on the following day completed the cast (Fig. 1). The thickness of the membrane varied in different parts, but in no place did this exceed one millimetre. It was of a pinkish grey colour coursed by red streaks; when examined in water it assumed a rugous aspect (Fig. 2). Microscopically it consisted of a fine network of fibrin, the meshes of which contained large numbers of white and red blood corpuscles, the former being in excess. Epithelial elements were totally absent (Fig. 3). Sections stained with Löffler's blue and by Gram's method show the presence of some number of micrococci, mostly arranged in pairs, but only very few are of the shape that suggests the diplococci of pneumonia. No bacilli resembling diphtheria bacilli have been seen in the membrane. The micro-organisms are most numerous on the side which was in contact with the gastric mucosa. The outer side of the cast is ragged; the fibrin has been dissolved by the gastric secretion which probably led to the separation of the exudation from the epithelium. It is of interest to note that the false membrane covering the pyloric end was the last to be shed, as one would have expected from the fact that the glands at that end of the stomach do not secrete so much [illegible] ast of the stomach was vomited [illegible] gastritis was not considered but [illegible] cessitated the adoption of rectal [illegible] ssibility of the diphtheritic origin of the disease was raised immediately upon the ejection of the membrane, nevertheless it was decided not to use diphtheria antitoxin. The advantage of the use of antitoxin on the fourth day of the disease is questionable and in a case which has already shed its membrane without that membrane possessing evidence of diphtheria it did not seem justifiable. This decision was fortunate, for if an injection of antitoxin had been given it would not have been easy to fully realise that the recovery was purely *post hoc* and not *propter hoc*. An attempt was made to maintain strength by giving a rational rectal diet. The form of nutrient selected consisted of 60 cubic centimetres (two ounces) of ox serum, 60 cubic centimetres of milk, and eight grammes (two drachms) of raw starch every four hours. Three grammes of chloretone were dissolved in every litre of serum. This had

[illegible] preserved the serum, it acted as a sedative the mucous membrane of the rectum, and it also caused the child to sleep for an hour or two after the administration of the injection, thus facilitating its retention and hence its assimilation. 360 cubic centimetres of serum, 360 cubic centimetres of milk, and 48 grammes of carbohydrate were introduced during the 24 hours, which diet possesses an energy value of over 500 calories, which is not much short of three quarters of what is necessary for a child three and a half years of age. When the pulse became feeble and the heart sounds assumed an embryonic type a few minims of tincture of nux vomica and of digitalis were added to the nutrient enemata. The efficiency of a rational rectal diet containing materials which we know can be absorbed by the large intestine was proved by the very slight loss in weight of the patient in spite of no food being given by the mouth for 10 days.

To Dr. H. D. Rolleston I am indebted for kindly criticism in writing out the case and for assistance in the recent literature of the subject. Mr. Robert MacQueen was good enough to take daily notes of the case and to draw two of the diagrams, and without his able assistance it would have een impossible for me to have recorded the case.

Wimpole-street, W.

PURPURA FULMINANS FOLLOWING SCARLET FEVER

By HUBERT E. J. BISS, M.A., M.D. CANTAB.,
D.P.H. EDIN. & GLASG.,
ASSISTANT MEDICAL OFFICER TO THE GROVE FEVER HOSPITAL.

THE diagnosis of the exceedingly rare condition from which the patient whose case is narrated below suffered is not by any means clear. It seems to me to correspond more closely to the condition which is described by Henoch under the name of purpura fulminans than to any other with which I am acquainted. It is noticeable, too, that one of the two ases related by him occurred after scarlet fever, as did also ne of two cases related by Ström and Arctander. Now, emorrhagic scarlet fever, as described in some works, is of eat rarity in this country at the present time; it is ubtful, indeed, if extensive cutaneous and subcutaneous morrhages ever occur in the early stages of the disease; whether the cases related in those works, in fact, were not actually cases of hæmorrhagic diphtheria. Hæmorrhages into the skin and subcutaneous tissue are met with not very infrequently in association with obstinate suppurative lesions after scarlet fever such as chronic suppurative lymphadenitis, suppurations in joints, and suppurations in and about the temporal bone. No such lesion obtained in this case. The child had a very severe attack of scarlet fever which did not present any unusual features and convalescence appeared to be established. He still had some ulceration of the soft palate, it is true, but the other symptoms had either passed off or had much abated, the temperature was settling down, and he was bright and comfortable. At this point cutaneous hæmorrhages in enormous abundance took place, accompanied by hæmatemesis, bloody stools, and oozing from the gums. In 36 hours from the appearance of the first hæmorrhages he was dead. The chief feature of the post-mortem examination was the state of the kidneys. These were transformed almost entirely into fat, a little blood-clot being found in the calices. This blood-clot, too, must have been very recent, as none was found lower down the urinary tract, even the urine in the bladder being free from blood. The kidney was a very different one from that associated with any variety of scarlet fever and no sign or symptom of nephritis occurred during life, except that albumin in small quantity was present in the urine for one day soon after admission. The change would appear to have been far more of the nature of an acute degeneration than of an inflammation, the homogeneity of the condition being very different from the sectional infiltrations seen in either the septic or glomerular type of scarlatinal kidney. No renal phenomena were noted by Henoch in the necropsies of his cases and Ström and Arctander do not state whether post-mortem examinations were made in their cases.

The sudden occurrence of these widespread hæmorrhages ests a very acute toxæmi [illegible] infection due to [illegible] elaboration of some toxic substance or the [illegible] some fresh organism, but what the nature of such body m have been and what determined its appearance [illegible] of the disease are speculations beyond the range of legitimat theorisation. A conceivable criticism is that these abundan hæmorrhages were but an advanced stage of the punctiform hæmorrhagic rash that occasionally follows the administration of animal sera, for diphtheria antitoxic serum had been given to this child in error. That this should be so is in the highest degree improbable, for not only has such an occurrence never been noted after the many thousand administrations that have come within one's purview, but this particular serum was used for injection into many children in the hospital without any analogous phenom ensuing.

The clinical and pathological features of the case may briefly summarised as follows.

A boy, aged three and a half years, was admitted into th Grove Fever Hospital on May 16th, 1902, certified to b suffering from diphtheria and on this supposition was give an injection of serum containing 24,000 units of diphtheria antitoxin. On examination, however, his trunk and limbs were found to be covered with a coarse, blotchy, punctiform erythematous rash; the throat was much reddened and very œdematous; the tonsils were coated with slimy exudation; the nasal mucous membrane was turgid and covered with muco-purulent discharge; the submaxillary lymphatic glands were considerably enlarged, and the tongue was dry and clothed with fur. Culture of the tonsillar exudation presented an abundant growth of streptococci. He was very ill till the 21st, when the temperature, had been continuous at 103° F., fell to 99°, and ther a general abatement of the symptoms. On that eve he became more feverish (the temperature being 102 and on the next day an urticarial rash appeared on trunk, due doubtless to the previous injection of ser Double otitis media, diarrhœa with green stools, and general desquamation ensued. On the 25th a furt eruption, a macular, purplish red one, was noticed about t knees, the ankles, and the elbows. By the 29th he was mu better; the glandular swellings had almost disappeared an there was no rash or diarrhœa. Bilateral otorrhœa, how ever, remained, and there was a little rhinitis, whilst a ulcer of the size of a threepenny-piece was found at the junction of the soft palate and the right anterior pillar of the fauces, though the tonsils were free from exudation and the tissues of the throat were but little swollen. From this time he improved rapidly till June 4th, notwithstanding that the temperature still fluctuated between 101° and 99°. On that day a vast number of pin point hæmorrhages were seen in the skin of both sides of the trunk, whilst the next morning the trunk and limbs were literally covered with these points, the upper extremities being so densely set with them as to appear almost uniformly purple. There were but few on the face, except on the inner sides of the eyelids where they were about the size of grape stones. Blood oozed from the gums, but there were no subcutaneous or subconjunctival hæmorrhages. His general condition was markedly worse. He vomited half a pint of red blood twice during the day and towards the evening he passed about that quantity of brightish red blood per rectum. He died soon afterwards.

Necropsy.—At the post-mortem examination, which was performed 30 hours after death, the cutaneous hæmorrhages were abundantly apparent and blood clot encrusted the lips, the nose, and the anus. Under the visceral pericardium and pleuræ a few punctiform hæmorrhages were seen, similar points being present under the endocardium of the left ventricle. The pleuræ each contained a few drachms of clear, pink fluid and the trachea and bronchi similarly tinted frothy mucus. The stomach showed many medium sized, submucous hæmorrhages, and both it and the intestines, which latter were deeply cyanosed, contained chocolate-coloured fluid; crimson, viscous blood filled the rectum. Beyond thickening and ulceration of the tissues of the throat nothing else remarkable was seen till the urinary system was examined. Both kidneys were a little enlarged, but their capsules stripped readily. On section the parenchyma was found to be transformed almost entirely into fat, which stained readily with osmic acid but not at all with iodine solution. There was no differentiation into cortex and medulla and a few faint pink streaks alone suggested the direction of the tubules. Several of the calices conta little blood-clot but none was found in the pelves or ureters. The bladder was distended with clear, yellow urine which gave no hæmoglobin reaction when tested with tincture of guaiacum and ozonic ether

I am indebted to Dr J E Beggs medical superintendent for permission to publish this case.

Tooting S W

SOME ADDITIONAL REMARKS ON THE ETIOLOGY AND DIAGNOSIS OF ACUTE DILATATION OF THE STOMACH

By H. CAMPBELL THOMSON M.D F.R.C.P LOND
ASSISTANT PHYSICIAN TO THE MIDDLESEX HOSPITAL.

IN my recently published book on the subject of acute dilatation of the stomach I have discussed at some length the different theories which have been put forward to account for the disease, and while in no way denying that some cases may be obstructive in origin I inclined to the belief that a primary paralysis of the organ must be regarded as the underlying cause in the majority of the cases. Those who support the theory that obstruction is the main cause consider that under certain conditions within the abdomen the superior mesenteric artery may exercise a constricting force upon the duodenum and the conditions necessary thus to produce this constriction are thought to be fulfilled by the displacement of collapsed intestine into the pelvis by which such a tension is put upon the mesentery that the cord like superior mesenteric artery becomes converted into a constricting band and obliterates the lumen of the duodenum There are many arguments against this theory which I have discussed elsewhere and need not again refer to here, but the main objection to the adoption of this view lies in the fact that the point at which distended bowel passes into collapsed bowel varies in different cases which it obviously would not do if the situation of the constricting force were a constant one as it would be in the case of the superior mesenteric artery I quoted cases in my book showing that sometimes only the first part of the duodenum shared in the dilatation while in others the distension extended some inches along the jejunum. More recently I have had an opportunity of making a necropsy upon a case in which acute dilatation of the stomach was accompanied by distension of eight feet of small intestine, the distension passing abruptly into collapsed bowel at that point. The appearance of the distended stomach and upper coils of intestine is shown in the accompanying figure which is reproduced from a photograph taken at the time of the necropsy and it is obvious that in this case the superior mesenteric artery cannot be considered as the constricting force nor were there any signs of any other constricting force having been present.

Acute dilatation of the stomach and upper eight feet of intestine

In the absence of any constriction a primary paralytic condition would seem to give an adequate explanation of this case, as it does in so many others and as I have before pointed out, there is no obvious reason why, if a primary paralysis is assumed to take place in the stomach, we should suppose that paralysis to be necessarily limited to the stomach. The nervous connexions between the vagi and abdominal plexuses are very complex and it seems reasonable to suppose that the paralysis which involves the stomach may in different cases extend variable distances along the intestine and such variable extension would adequately explain the fact that the distended bowel terminates at different levels Reference in my former writings will also be found to the probable relationship between acute dilatation of the stomach and the paralytic distension of the intestines which occurs during cases of acute peritonitis It is, of course common and indeed usual, to find the intestines distended in cases of peritonitis and there can be little doubt that the distension is due to paralysis of the gut walls consequent to the inflammation of the peritoneum. While in these cases distension of the intestine is usually the predominating feature, both during life and after death the necropsy often shows that the stomach has also to some extent participated in the condition and occasionally the gastric symptoms form the most prominent feature of the case and may for the time even mask all the symptoms of the underlying peritonitis. This fact assumes considerable importance when it is remembered that peritonitis is the condition which clinically most closely resembles acute dilatation of the stomach and for which many primary cases of the latter have been mistaken We have thus in every case in which symptoms of acute dilatation of the stomach occur after an abdominal operation or under other conditions in which [peritonitis would be likely to arise, to decide whether the dilatation is a primary condition or whether it is only the predominating feature of a general peritonitis. A case which I recently had an opportunity of seeing with Dr Comyns Berkeley well illustrates this condition and also the difficulty which one may have in arriving at a correct diagnosis when there is a possibility of peritonitis co-existing, although there may be no obvious reasons which would lead one to suspect its presence.

The patient was a female, aged 32 years, and had previously had five children. She had passed uneventfully through a sixth pregnancy and on the evening of Jan 5th, 1902, intermittent pains came on and it was considered that labour had commenced On the evening of the 7th the pain became continuous and more distressing and about the same time the patient commenced to vomit some yellow fluid The pain and vomiting continued and were for some hours accompanied by alarming symptoms of collapse, but the child was safely delivered and after that the symptoms subsided, the pulse fell from 130 to 80 and the temperature was normal. This respite was, however, very brief and six hours later the pulse had risen to 136, the respirations were 60, and there was continuous vomiting and great collapse but no pain It was at this juncture that Dr Berkeley first saw the patient and on examination he found signs indicating great dilatation of the stomach. The organ appeared to reach within two inches of the pubes The liver dulness was partially obliterated and the lower lobe of the left lung was pushed up, so that the percussion note over the lower part of the left side of the chest was hyper resonant. The diagnosis was further confirmed by the elicitation of a marked succussion splash and by the presence of frequent vomiting of large quantities of yellowish fluid without any effort. Dr Berkeley kindly asked me to see the case and we came to the conclusion that the predominating symptoms were those of acute dilatation of the stomach and from the apparently normal confinement which had taken place only a few hours before and in the absence of abdominal pain and tenderness there did not seem any justification for supposing there was any underlying cause other than shock. We therefore, with a view of alleviating the more distressing symptoms, passed a soft tube into the stomach and drew off over three pints of fluid, after which the patient for a time expressed herself as considerably relieved but she eventually died about six hours later A post mortem examination showed the presence of general purulent peritonitis which had arisen from the rupture of an ovarian abscess The stomach was moderately distended and had evidently undergone some contraction after the evacuation of the fluid, as has frequently been noticed in other cases

In this instance, then, the acute dilatation of the stomach was secondary to the peritonitis and therefore merely a symptom of a much graver condition It is, of course, most important from the point of view of both prognosis and treatment to distinguish, if possible, between such a case and one in which the stomach factor is either the primary condition or the threatening fatal complication of some less serious malady

Queen Anne street W

NOTES ON THE THERAPEUTIC USES OF THE SALSOMAGGIORE WATERS[1]

BY G SANDISON BROCK, M D EDIN & ROME, F R S. EDIN.

IN the admirable report of THE LANCET Special Analytical and Sanitary Commission on the Iodo-bromo saline Waters of Salsomaggiore[2] reference is made to my own observations bearing upon the therapeutic uses of the waters At the risk of repetition I shall here endeavour to arrange these as far as possible in the order of their importance and at the same time to supplement to some extent what has already appeared in THE LANCET's report.

The uses to which the waters of Salsomaggiore are now put, as well as the methods of employing them, have been largely determined by the nature and the mode of treatment of the first few cases recorded by Berzieri, the village practitioner of Salsomaggiore, to whom the original inspiration came (in 1839) of utilising them for therapeutic purposes The first case in which he used the baths was one of caries of the bones of the foot, no doubt tuberculous, and to this day the waters continue to enjoy the reputation earned by the success of that treatment in a great variety of tuberculous lesions, whether in bones joints, glands, or skin. It is, perhaps, chiefly for this class of cases that the waters are most esteemed amongst the common people in Italy, the various communes sending for treatment to the sanatorium of Salsomaggiore batches of patients, mostly of this kind, every three weeks throughout the summer and paying their expenses No better testimonial to the efficacy of the waters could be given than the fact that the same communes, encouraged by the great benefit derived, continue to send such patients year after year, and that in many instances these patients return from time to time of their own accord and at their own expense when assailed by recurrences of their maladies No doubt the change of air and the better food which such patients obtain at Salsomaggiore contribute largely to the success of the treatment in these cases, nevertheless, they must still be regarded as amongst the most promising of those indicated for the Salsomaggiore cure.

The alterative, absorbent, and healing properties displayed by the waters in these scrofulous cases naturally led to an extension of their use to all affections where in connexion with a localised morbid process there existed open sores, sinuses, inflammatory swellings, or exudations Their beneficent action in the chronic stages of inflammatory diseases forms, indeed, the basis of their fame at the present day In the acute stages they are generally regarded as contra-indicated (although this is by no means a settled question), but the acute stage once over all are agreed that great benefit is derived from their use in such affections. In cases of appendicitis where a certain amount of pain and swelling remain after an acute attack or where an abscess has been opened or has burst leaving painful adhesions or exudations behind in the neighbourhood of the colon the absorbent and healing effects of the baths are often very remarkable For sequelæ of peritonitis, of pleurisy, and of synovitis, for arthritic troubles after dislocations, for the thickening of bone and periosteum following fractures and other injuries, or indeed in most chronic inflammatory processes accompanied by pain, stiffness, swelling, or deformity, the soothing or stimulating properties of these waters, or of applications of the mud deposited from them, are found to be highly beneficial. Especially satisfactory are the results obtained in arthritis consequent upon acute rheumatism or relapses of that malady, as well as in that occasioned by gout. In these cases the baths exercise a strongly soothing and absorbent influence locally, and at the same time stimulate powerfully the excretory functions of the body, enabling the system to throw off rapidly the poisonous waste products by the skin, the lungs, and the kidneys

The remarkable absorbent effects of the waters have led to their very extensive employment for diseases of women It is, perhaps, in this connexion that they are most known and made use of in Italy amongst the well to-do classes All possible varieties of gynæcological ailments find their way to Salsomaggiore, and it is really wonderful how many different maladies in that large category of diseases find relief from the treatment. This is explained by the fact that the greater number are of an inflammatory nature, in the chronic stage so favourable to the healing action of the waters Amongst those most amenable to the treatment are the various inflammatory affections of the uterus and adnexa—to wit, cervicitis, endo-, para-, and peri metritis, salpingitis, pelvic peritonitis, and pelvic cellulitis Lacerations, displacements, and new growths may derive benefit as far as certain secondary effects produced by them are concerned. Sterility is often cured, as might be expected when the cause producing it is susceptible of removal, by a course of the baths Functional derangements of the sexual organs of the most diverse kind often yield to the treatment —such as amenorrhœa, menorrhagia, dysmenorrhœa, or irregularity of menstruation—a result due probably to a general tonic effect which the waters exercise upon the nutrition of the body

The large quantity of iodine present in the waters has suggested their use in diseases due to infection by specific germs other than that of tubercle, and they are, in fact, found of great value in the later stages of syphilis (both for the secondary manifestations in the skin, the mucous membrane, and the periosteum, and for the tertiary changes in the bones and the organs), as well as for the sequelæ of gonococcic infection, whether in the genital organs themselves (as urethritis, orchitis, metritis, &c.) or in other parts of the body (post-gonorrhœal rheumatism, arthritis, and synovitis)

A considerable number of neurasthenic and anæmic patients also benefit, often quite remarkably, by the Salsomaggiore treatment. In those cases the restfulness and quiet of the place itself must greatly contribute to the successful result, but the soothing effects of the baths and the alterations which they are capable of producing in the nutritive processes of the body through the nervous system and the circulation have also, we may be sure, an important share in bringing it about.

---

[1] For much information regarding the therapeutics of the waters I am indebted to my colleague at the baths Professor Zoja.

[2] THE LANCET, July 12th 1902, p 94

A popular belief has gradually arisen in the power of the waters to give tone to the mucous membrane of the respiratory tract and so to prevent attacks of coryza and ordinary bronchial colds. Many go through the "cure" regularly every summer with the idea that they are thus insured against such attacks for the whole of the ensuing year This virtue is especially attributed to the inhalations which form a great feature of the treatment as it is now carried out at Salsomaggiore, and undoubtedly they have proved to be a most valuable adjunct to it, both by means of their local effect upon the parts with which they come into contact as well as by an indirect action exercised through the blood upon the system generally Whilst there seems to be as yet no satisfactory evidence that any absorption of the saline and other constituents of the waters takes place through the skin during bathing there can be no doubt that during a prolonged stay in the inhalation room a certain amount of the iodine and other ingredients of proved therapeutic value does actually enter the blood, and it is therefore reasonable to suppose that their presence there may exercise a distinct influence upon morbid processes in the body and contribute appreciably to their cure. The ordinary course of baths is for this reason often supplemented by the use of inhalations even when there is no local affection of the respiratory apparatus calling for their employment. But where such exists excellent results are frequently obtained either by directing a spray of the *acqua madre* (deprived of some of its calcium and magnesium salts) on to the affected part, or by causing the patient to breathe for a considerable length of time the atomised natural water in the inhalation room. The direct spray is used for affections of the upper air passages (rhinitis, pharyngitis laryngitis, and trachitis) where the lower part of the respiratory tract is involved as in chronic bronchitis and bronchial asthma, a prolonged stay in the inhalation room is also frequently beneficial. In chronic catarrhal conditions of the conjunctival mucous membrane a spray or douche of the diluted *acqua madre* may be used with benefit. In all cases where the direct spray is used it is essential to begin the treatment with weak solutions of from 1° to 2° Beaumé, gradually increasing the strength to 7° or 8° Beaumé. The use of the direct spray and of the inhalation room is often combined in these catarrhal affections for both have a beneficial effect by soothing irritation reducing congestion and swelling liquefying and loosening thickened adherent mucus, and thus bringing about a healthy condition of the mucous surfaces.

When a powerful local effect is desired—as, for instance, in cases of glandular enlargements arthritic joints, injuries by sprains damage to parts by old wounds dislocations, fractures, &c.—the Salsomaggiore mud or *fango* is made use of This mud collected from the tanks into which the springs flow on emerging from the artesian wells, is saturated with the salts of the waters and strongly impregnated with the oily bituminous ingredients contained in them. Applied hot in the form of a poultice over or around the affected part it has an excellent effect in soothing pain reducing swelling and removing stiffness. These mud applications are kept on for from 20 minutes to half an hour and are scraped off just before the patient enters his bath. They are a most useful part of the Salsomaggiore treatment and are much in favour amongst patients on account of the speedy relief which they generally afford

The indications for the Salsomaggiore treatment may be summed up briefly as follow —

1. Tuberculous disease in bones, joints, glands or skin
2. Gynæcological ailments, more especially those of an inflammatory nature.
3. Rheumatism and gout, especially the arthritis associated with them.
4 Inflammations in general in the chronic stage catarrhal affections of eyes ears nose mouth and throat, and bronchitis.
5. *Various results of injuries, wounds &c.*
6. Tertiary syphilis and post-gonorrhœal affections.
7 Neurasthenia, neuralgia, and neuritis.
8. Anæmia and retarded convalescence from acute illnesses.

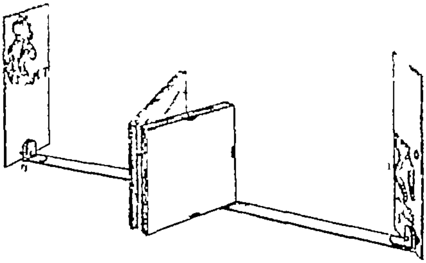
Rome

THE TREATMENT OF CONVERGENT SQUINT IN HOSPITAL PRACTICE

BY G T BROOKSBANK JAMES, F R.C.S. ENG
ASSISTANT SURGEON ROYAL EYE HOSPITAL, SOUTHWARK

THIS important subject is far from receiving at the present day the attention which it merits. I do not refer to the question of operation in this disorder as there has never been a tendency to under activity in that department. I allude to the well known fact that no systematic method of orthoptic training is usually adopted owing to the time and trouble necessary to carry out such treatment efficiently The constant rush of out patient work and the demand on the time and energies of ophthalmic surgeons for many other purposes are responsible for the neglect of this valuable means of cure.

The backbone of orthoptic treatment is the stereoscope. Many excellent forms of this instrument have been invented and can be used in high degrees of squint. These cannot be of service for hospital purposes for one reason—they are prohibitive in price It has always seemed to me that perhaps the most important reason why the treatment of convergent squint is so unsatisfactory is that no stereoscope of suitable construction and small cost is at the command of the ordinary hospital patient for home use If the surgeon finds it impossible to carry out the treatment he may safely delegate this to the patient's mother if she is provided with a cheap and convenient instrument for the purpose and is shown its use beforehand. I have devised the little stereoscope shown in the woodcut for use in hospital practice. It is constructed of the cheapest materials and can be used in cases of convergence of high degree I am well aware of its imperfections which are mostly such as are inseparable from its cheapness. It consists of two mirrors eight centimetres square united by a hinge. To the lower border of each mirror is attached a brass bar 15 centimetres long with a clamp obliquely placed at its extremity The bar is freely moveable but can be fixed at any angle to the mirror by a toothed stay which gives additional firmness. The angle at which it is usually placed is 115° When not in use the hook is undone and the instrument can be folded into a convenient shape. The stereoscopic figures employed vary much in size according to the visual acuity and youth of the patient. Duplicate coloured scrap figures on glass slides are very useful parts of each figure having been carefully cut out. It is of great service to use letters on each glass slide alongside or across the figures and leave gaps between them On fusion in the mirrors they are seen as short words such as "Tom," "Bob" &c. and act as valuable controlling tests in children who can read. Almost any object the ingenuity of the experimenter may devise can be adapted to the instrument. The ordinary photographic views in the shops can be employed. They are first cut in half and transposed right half in the left clamp and *vice versa* controlling dots are useful, of course, with these. The oblique position of the clamps presents the objects nearly square *in the mirror* to the observer and facilitates their fusion. Our usual routine treatment in cases of squint occurring in hospital practice is as follows The refraction is first accurately estimated under atropine two pairs of glasses are then ordered The first pair contains the patient's full distance correction under a mydriatic and are for constant



use, the second pair adapt him to a distance of 25 centimetres, approximately that at which the objects are viewed in the mirrors. The lenses in the latter pair of glasses are decentred inwards Stereoscopic training is at once resorted to when the glasses are procured. The patient's mother is first shown the use of the instrument. The child is then shown the two separate halves of the figure on the slides. The latter are then superposed and he sees the whole figure and is told he must look for it in the mirrors. He is now placed on a chair facing the windows and the teacher stands behind holding the angle of the mirror in front of the patient's nose and open at about a right angle. The head is steadied by the teacher's wrists in this position. If the patient sees the separate halves of the object simultaneously the mirrors are gently manipulated until he fuses them and I find that if left alone with the mother the child can often accomplish this sooner than with anyone else. The next step is to train him to relax his convergence in the interests of binocular vision and this is often a tedious business, but steady improvement usually takes place if he is exercised twice daily by the mother and presents himself every fortnight at the hospital. Herein lies, I think, the chief argument for the use of a stereoscope at home. The fusion faculty in a young child may be readily aroused and preserved by occasional exercises, but to overcome the tendency to converge unduly requires many such exercises and these at short intervals In the cases where the patient is unable to see both objects simultaneously in the mirrors, the one seen may be thrown into shade by tilting the mirror, and the stay on the opposite side being gently released from its attachment the bar may be moved independently to attract attention

With regard to the age at which such exercises may be begun there is no definite rule, much depending on the idiosyncracy of the child Glasses should be ordered, however, and stereoscopic training should be resorted to at the earliest age possible in each individual case. Other methods of orthoptic training, such as bar reading, are most useful with older children, but cannot contend in point of accuracy with the stereoscope. I would point out, however, the advantage of teaching a child its letters at the earliest age possible, as a modified form of bar reading can then be adopted with large letters and is of the greatest value. In cases of monocular squint I cover the good eye until the squint becomes alternating at the will of the patient, though in such a case the visual acuity in one eye may remain much below that of the other In such a case stereoscopic training should also be adopted as a modified though useful form of binocular vision may be procured even though the sight of one eye differs greatly from the other I do not believe, however, in the prolonged exclusion of one eye after a fair effort has been made to restore the visual acuity of the other, nor do I think that such wearisome treatment renders the patient more likely to learn to fuse in the *stereoscope*. With regard to the question of operation tenotomy of an internal rectus is necessary in most old cases of monocular squint and probably in these alone Advancement of each external rectus has now many advocates and is far preferable in the younger cases. The earlier stereoscopic training is resorted to, the greater the care taken in its details, and the more constant its employment the less frequently will the surgeon have to resort to operative treatment in cases of convergent squint.

Wimpole-street, W

CHRONIC SPHENOIDAL SUPPURATION SOME OBSERVATIONS ON OPERATION AND CICATRISATION

By DAVID McKEOWN, M.A., M.D, M.Ch. R.U I,
SURGEON TO THE MANCHESTER EYE AND EAR HOSPITAL.

THE treatment of chronic suppuration of the sphenoidal sinus ranges itself under three heads (1) irrigation and insufflation of powders, (2) breaking down the anterior wall and curetting the cavity, and (3) extending the operation by removing a part of the floor

Some surgeons advise against operation on account of its difficulties and dangers. The depth of the sinus from the surface, the small and uneven calibre of the channel for manipulation, the irregularity of contour of the which may present large pouches or diverticuli, important intracranial structures in close with it, and the breaches (anatomical or which may be found in the bony wall—all countenance to this view But an unyielding cavity (bony walls) filled with retained pathological (solid and fluid) and the lining membrane of which suffered the usual degenerative changes cannot be cured irrigation through an opening at a considerable height the floor Hence the attempt to treat the sinus on the which surgical experience has shown to be removal of pathological products and drainage. This was sought by breaking down the anterior wall and the cavity Did the means attain the end? the removal of the pathological products it is to observed, having regard to the anatomical conditions to the pathological changes which may have taken that curetting must be considered as a delicate procedure that in individual instances there may be doubt as to it has been efficient—whether the diverticula and pouche have been thoroughly explored In respect of the effected the method of operation was also open to objectio The opening obtained does not always reach the level of lowest part of the sinus. To remedy this defect it was suggested that a part of the floor should be removed Does th enlarged operation always secure thorough drainage? I hav performed it in three cases, removing (in addition to whole of the anterior wall) as much as I could—both anter posteriorly and laterally—of the floor I employed Grunwald' forceps and burrs driven by a dental engine. The bur were very useful, enabling portions of bone to be remove which on account of physical difficulties could not be with by the forceps. In two of the cases (mentioned hereafter as No 2 and No 3) the opening effected almo reached the level of the lowest point of the floor, but i the patient mentioned hereafter as No 1 it did no although the opening was large, the great depth and rapidly increasing thickness of the bony floor limiting th operation. In all the cases the lateral margins of th opening were flush with the septum and the outer wal Whether or not the drainage in such cases is effectu depends not merely on the presence or absence of depressions or pouches but also largely on the character of the healing process which sets in This suggests the question, Wha is the condition of the sinus when as the result of treatmen it has ceased to be a discharging cavity? Has it lined by a more or less thin dry membrane or has it becom wholly or largely occupied by granulation tissue? Eve where the opening has been the largest possible the surgeo would probably find it a difficult matter to describe th condition of the cavity at a given moment durin cicatrisation.

As the cases which I have mentioned bear upon the point which have been raised I shall now state a few fact concerning them The patients were a man, aged 30 years and two young women, aged 21 and 19 years respectively In all (left side) there were nasal polypi (in No. 1 and No. these were so numerous and bulky as to fill a nostril o large dimensions—the septum was displaced—and also t encroach on the post-nasal space), in all the ethmoidal cell and the sphenoidal sinus were involved, in all the middl turbinated bone and the polypi were removed, the ethmoida cells were broken down and curetted, and then the anterio wall of the sphenoidal sinus was removed and the cavit curetted. In No. 1 and No 3 the floor of the sinus was no removed for several weeks, but in No 2 the anterior wall an the floor were removed at the same sitting I was forced t remove the floor in No 1 by finding on one occasion tha the quantity of secretion on dressing was greater than coul be accommodated in the cavity as revealed by exploration after removal of the anterior wall From this circumstance it was inferred that there must be a pouch s situated as to escape detection and necessitating for exploration and treatment a larger opening This view was foun to be correct when the larger part of the floor was removed It was then seen that there was a large deep pouch, latera to the plane of the outer wall of the nose, formed by a bon septum which was beyond the effective reach of the forcep and burr, so that for the pouch I was limited to scraping b a ring knife. In all the cases the ethmoidal seat of operation healed quickly and satisfactorily, in all granulatio tissue was formed in such quantity in the sinus and aroun its artificial opening that, large as the aperture was, it becam so reduced both antero-posteriorly and laterally that I thought it insufficient for drainage and dressing and likely to close. Hence, on several occasions I have by the cautery enlarged the opening almost to its greatest dimensions and destroyed part of the granulation tissue (in one of the cases I have also used chromic acid).

In all the cases the discharge is now small in quantity but can one be sure that none is penned up either in anatomical pockets or cicatricial pockets—i.e. pockets formed by the coalescence or contact of opposing granulations leaving cavities behind unlined by dry membrane? Judging from what takes place in other more accessible parts of the body such an occurrence must be regarded as not improbable. My experience of radical mastoid operations—extending to about 200—shows this clearly Here the field of operation lies before the eye, pathological products can as a rule be completely removed and the wound cavity in its entirety and throughout cicatrisation is generally open to inspection In some cases the cicatricial tissue produced is small so small indeed that the healed cavity is almost as large as the operation cavity which has been covered by a thin layer of dry membrane. In other cases the cicatrised cavity is small, very much smaller than the operation cavity granulation tissue having been abundantly produced. Between these extremes there are many grades. The free production of granulation tissue after mastoid operations leads at times to trouble. Cases are not unusual in which it is difficult to keep opposing surfaces apart until the reparative process immediately behind (deeper) has been effected—in other words, to prevent the formation of pockets This difficulty I have experienced in cases where at the time of operation I have paid special attention to the walls of the cavity with a view to guard against this contingency by so far as possible removing ridges and avoiding depression Again pockets may be in existence for considerable periods without manifesting their presence in one case a pocket requiring treatment was found after months of what seemed complete cicatrisation. In studying sphenoidal cicatrisation our experience of mastoid cicatrisation should not be forgotten neither should it be overlooked that the latter is more under the surgeon's control than the former for in mastoid cases the surgeon is more favourably circumstanced (*a*) to remove the whole of the diseased products and tissues, (*b*) to render the cavity more favourable to healing by removing ridges and (*c*) to control cicatrisation by caustics and dressings It is evident that the question of cicatrisation after even the most skilful operation on the sphenoidal sinus may be of great importance and that a cure may not have been effected although for a considerable period there has been no discharge from the sinus.

Note—Although the subject of this paper is chronic suppuration of the sphenoidal sinus it is desirable that I should give some additional facts relating to the three cases mentioned above, showing the extent of the area involved in the pathological process, in order that their character and significance may be more fully understood. In No 1 there was on the left side (in addition to the ethmoidal and sphenoidal suppuration) suppuration of the frontal sinus and the antrum, both of which have been operated on from the outside. On the right side there are some small polypi and pus and it is not unlikely that some of the air spaces will have to be dealt with. The nasal trouble in this case is believed to date from boyhood. In No. 2 there were on the right side nasal polypi and suppuration of the ethmoidal cells and sphenoidal sinus the polypi and middle turbinate were removed the ethmoidal cells were broken down and curetted and the anterior wall of the sphenoidal sinus was broken down and the cavity curetted with an apparently satisfactory result. On this side the frontal sinus is to be opened. In No. 3 the left frontal sinus requires to be opened but for domestic reasons it has to be postponed.

Manchester

CONVALESCENT HOME AT LLANDUDNO—The foundation stone of a new convalescent home was laid at Llandudno on July 23rd by Lady Forester The funds for the erection and endowment of the institution are derived from the estate of the late Lady Forester who bequeathed nearly £750 000 for the erection of hospitals and a convalescent home for the benefit of the poor of Shropshire and North Staffordshire.

WESTMINSTER HOSPITAL

A CASE OF ANEURYSM OF THE SECOND AND THIRD PARTS OF THE LEFT SUBCLAVIAN ARTERY, LIGATURE OF THE FIRST PART RECURRENT PULSATION SIMULTANEOUS LIGATURE OF THE INFERIOR THYROID VERTEBRAL, AND THIRD PART OF THE AXILLARY ARTERIES RECOVERY

(Under the care of Mr CHARLES STONHAM C.M.G.)

THE treatment of an aneurysm of the second or third part of the subclavian artery on the left side stands in rather a different position from that of an aneurysm of this vessel on the right side of the body for on the right side there is no intrathoracic portion of the subclavian and ligature of the innominate artery is certainly a much more serious operation On the left side, however the first portion of the subclavian artery is much longer than on the right, and there is ample room for the application of a ligature internal to the origin of its branches. The following case is remarkable not merely for the successful application of a ligature to the intrathoracic portion of the subclavian but also for the subsequent ligation of several of its branches and of the axillary artery with an ultimately successful result. In estimating the prognosis of such operations no stress should be laid on the statistics of pre-antiseptic days for sloughing of the sac and secondary hæmorrhage from the site of application of the ligature were the chief causes of failure and nowadays these are practically eliminated. We congratulate Mr Stonham on the success of his treatment.

A man aged 43 years was admitted into Westminster Hospital on April 13th, 1899 in consequence of a swelling in the root of the neck on the left side The patient had contracted syphilis 14 years previously and 10 months before admission he had a gumma on the left calf one on the inner side of the left thigh and a third on the left forearm In November 1895 he was admitted into St. Peter's Hospital Bristol in consequence of bronchitis and considerable hæmoptysis", he was an in-patient 10 months when he was discharged as suffering from phthisis and being incurable. He was then admitted into the St. George's Infirmary Fulham road, and improved considerably On his discharge he resumed his work as a carpenter and worked regularly until he came to the hospital, although he was troubled with his chest and a cough." He had also suffered from piles and right-sided sciatica. As regards his present illness five months before admission the patient experienced an aching pain in the upper part of the left chest and noticed a swelling of about the size of a walnut at the root of the neck above the left clavicle. This swelling was at first very tender but the pain soon passed off and the patient put pressure on the swelling for two or three days, after which according to him it disappeared but suddenly reappeared two or three days later This swelling gradually increased in size but although at first he occasionally suffered acute stabbing pain in the left chest and down the left arm this did not trouble him latterly and he continued his work until April 12th, 1899 the day before his admission.

On April 17th the patient was thin and had a worn expression. The chest was badly formed and its mobility was markedly deficient The percussion note was somewhat impaired at the apex on both sides there were no moist sounds or other abnormality there was no expectoration. The heart was normal. The arteries were not rigid or particularly tortuous. The abdominal viscera were normal The urine was of specific gravity 1016, acid and contained no albumin or sugar The ends of the fingers were clubbed especially on the left hand. There was a swelling in the left supra-clavicular region of about the size of a duck's egg rising well above the clavicle and situated over the third and part of the second part of the subclavian artery, extending forwards beneath the clavicular head of the sterno mastoid to near the middle of the sternal head. The swelling occupied the whole of the supra clavicular fossa, but there was no dulness below the clavicle indicative of its extension in that direction, although it is true that there was deficient resonance at the apex of both lungs, this deficiency was equal on both sides The swelling was expansile and there was a very distinct systolic bruit and thrill. The diagnosis was aneurysm affecting the convexity of the second and third parts of the left subclavian artery Dr W H. Allchin kindly saw the case with Mr Stonham with the view to ascertain the condition of the thoracic viscera, he was unable to detect any organic mischief After carefully considering this case in all its bearings and being convinced that rupture of the sac would occur in a short time, Mr Stonham determined to attempt cure by proximal ligature in spite of the general opinion that such an operation should not be undertaken

An operation was performed on April 26th The patient was placed under chloroform and Mr Stonham proceeded to tie the vessel in the thorax, being most ably assisted by Mr E. P Paton The shoulders being somewhat raised by pillows, the head thrown slightly backwards, and the face turned to the opposite side, a vertical incision about six inches long was made parallel to, and just outside, the sternal head of the sterno-mastoid, the centre of the incision being placed over the sterno-clavicular articulation. The upper part of this incision exposed the muscular fibres while the lower half was made right down to the sternum A second incision was then made along the inner half of the clavicle, the knife being made to cut down to the bone. The clavicular head of the sterno-mastoid was separated from its attachment, the clavicle being closely "hugged" all the time, this part of the muscle with the upper triangular flap of skin was very carefully turned upwards and outwards. A small portion of the pectoralis major was now separated from the sternum and clavicle and was turned with the second triangular portion of skin downwards and outwards The parts were very vascular but no vessel of any importance was encountered, all bleeding points were at once clamped and tied, the most troublesome one being a small perforating branch in the first intercostal space The clavicle was now very carefully sawn about one inch or rather more, from its sternal end, the division being completed with bone forceps, the sternal portion of the bone was isolated by means of a raspatory and by the knife, both instruments being kept as close as possible to the bone so that in point of fact the resection was practically sub-periosteal During the division of the bone the deeper parts were protected by a retractor The floor of the wound was now seen to consist of a portion of the clavicular periosteum a layer of the deep cervical fascia and muscular tissue By means of two pairs of dissecting forceps the outer edge of the muscular layer was clearly defined, the muscles being the sterno-hyoid and the sterno-thyroid, these were drawn inwards. Further blunt dissection revealed the carotid artery running vertically upwards along the inner border of the wound which was now becoming very deep On the outer side and below was the dome of the pleura covered by the junction of the subclavian and internal jugular veins and a short piece of the left innominate These veins were carefully drawn downwards and outwards, when deeply behind them about two thirds of an inch of the subclavian artery were revealed, surrounded by a little loose fat. The thoracic duct was not seen nor were any nerves or veins other than those mentioned Little ifficulty was experienced in passing an ordinary aneurysm eedle armed with salicylic floss silk round the vessel from ithin outwards, the finger was then placed upon the vessel hich was apparently quite healthy and highly elastic) nd the loop of the ligature was drawn tight beneath it, the dial pulse and all pulsation in the aneurysmal sac were rested, and the ligature was then tied with a surgeon's ot, the ends being cut quite short. The ligature was only d with sufficient force to occlude the artery, not to rupture inner coats, it was situated behind the sterno-clavicular t about half an inch from the aneurysmal sac The deep nd was carefully dried and the displaced structures were wed to resume their normal position the sterno-hyoid sterno-thyroid muscles completely hiding the artery from

The skin wound was closed with silkworm gut and ehair interrupted sutures a short gauze drain being d in the middle of the incision as deep as the sterno- and thyroid muscles. The wound was dressed with

the gauze drain was removed Slight pulsation, not
was felt in the sac, which was much smaller and ha
the 9th the stitches were removed, the wound wa
healed, it was now covered with a collodion dressi
sac was smaller, denser, and more localised, slight
could be felt in it but could not be seen The rad
was more distinct. From May 9th to June 2nd the
was kept quiet in bed, still taking potassium iodi
the latter date the pulsation in the sac was di
excentric and the sac had somewhat increased in
the outward direction Until a week before Jun
this increased size of the sac slightly diminishe
now the pulsation was more evident, especially
upper and outer part The patient also complain
pain in the shoulder and down the upper arm The
pulse was very good but delayed in time. On the
equable and continuous pressure was applied to the
by means of marine sponges and bandages. On the
there was no result from the pressure and it was conseque
discontinued, indeed, the sac was clearly increasing
wards and upwards and the pulsation was becoming m
evident. Dr Allchin kindly saw the case with Mr Stonh
and it was decided that something further must be do
On the 27th the left hand was slightly swollen and congest
and the patient complained that he could not move t
fingers properly

On June 28th the vertebral, inferior thyroid, and the thi
part of the axillary artery were ligatured. A vertical incisio
was made just external to that employed for the previou
operation and was carried further upwards along the oute
border of the sternal head of the sterno-mastoid. A second
incision was made from the lower end of this outwards along
the line of the clavicle and this triangular flap of skin was
then turned upwards and outwards, the remains of the
clavicular head of the sterno-mastoid were drawn out-
wards and the internal jugular vein was exposed Blunt
dissection external to the vein exposed the anterior scalene
muscle and phrenic nerve. The jugular vein was drawn
inwards and the muscle outwards The transverse pro-
cess of the sixth cervical vertebra was exposed A vess
of no great size was now defined in the position of th
vertebral artery and was ligatured with silk, the ligatur
unfortunately broke, dividing the vessel which was
secured with difficulty and tied at both ends No other
vessel could be found in this situation, though the foramen
through the transverse process could be clearly defined. A
second vessel—the inferior thyroid artery—was also tied
A piece of gauze was carried to the bottom of the wound
as a drain and the incision was sutured with horsehair
Ligature of these vessels materially diminished but did
not arrest the pulsation in the sac and it was therefore
determined to apply a distal ligature to the third part of the
axillary artery, and this was accordingly done just above the
subscapular branch and was followed by complete arrest of
the pulsation

On June 29th the patient was comfortable, sickness had
been very slight. The circulation in the fingers was good.
The wound in the neck had oozed a little and the dressing
was stained, this had been packed On the 30th the wound
was dressed and a smaller plug of gauze was put in the
cervical wound The wounds were healthy On July 3rd
the patient was progressing satisfactorily and was kept on
fluid diet. The dressings had not been touched. The
circulation in the arm was good but no pulse was present
either at the wrist or the elbow On the 4th the bowels
were opened On the 5th there had been

progress. The wound was dressed and the sutures and gauze plug were removed. No pulse was to be felt. The aneurysm was decidedly smaller harder, and denser, there was no trace of pulsation in the sac. On the 11th the wounds were soundly healed. The aneurysm was still smaller and harder over it slight pulsation could be felt along a transverse line (? the transverse cervical artery). The radial pulse was just perceptible. The further progress of the case was uninterrupted. The sac gradually diminished in size and the pulse became stronger in the radial. The patient complained for a few days of stiffness in the fingers He got up for the first time on August 6th and soon went to a convalescent home.

Remarks by MR STONHAM.—In November I saw the patient and could find absolutely no trace of the sac—indeed, examination by surgeons who did not know the case did not lead to a diagnosis as to what operation had been performed and why The complete disappearance of the sac is most remarkable. The space between the sawn end of the clavicle and the sternum contained a little fluid which I thought was probably synovium there was no pain or redness. The movements of the arm were necessarily weak. The patient had suffered from rheumatism for years and at this time there was effusion into the left ankle-joint. In other respects he was quite well. I have seen this man as lately as March 1902, and he continues quite well. He is doing light work as a carpenter

HULL ROYAL INFIRMARY

A CASE OF GUMMATOUS PERITRACHEITIS PENETRATING THE AORTA, WITH PROBABLY SYPHILIS OF THE LUNG

(Under the care of Dr FRANK NICHOLSON)

FOR many years it was disputed keenly whether syphilis affected the lung at any time and it is not improbable that many of the earlier cases of pulmonary disease which were ascribed to syphilis were really tuberculous in origin. It cannot at present be doubted that syphilitic lesions, though rare, do occur in the lung of these gummata are certainly the most common. The value of potassium iodide in the treatment is indubitable but the drug must be persevered with and must be given in sufficiently large doses[1] but mercury must be administered with great care in any case which may be tuberculous in nature. In all probability the lung affection in the following case was syphilitic For the notes of the case we are indebted to Dr F C. Eve house physician.

The patient was a well nourished man aged 38 years who had formerly been in the army for 12 years. Six weeks before admission he was in perfectly good health when he caught cold after violent exertion (running) Two days later he was in bed suffering from cough pain in the chest, cold shivers, vomiting and anorexia, and he brought up yellowish expectoration which rapidly became offensive These symptoms became aggravated and on the strength of a gumma on the sternum he was admitted on the surgical side under the care of Mr E. Harrison. Here the patient was treated with a short course of potassium iodide without improvement to the gumma or to the symptoms in the chest. Dr Frank Nicholson's opinion was then invited and as there were loud tubular breathing bronchophony and dulness on the lower part of the left lobe in front the case was transferred to the medical side under his care. The gumma on the chest had only been noticed for six weeks Near it were three scars where similar lumps had been excised a year ago in this infirmary with the diagnosis of necrosis of the ribs There was no history of phthisis or of swallowing a foreign body In face of the patient's long military career an inquiry as to syphilis was considered supererogatory

On admission the patient looked ill. His chest moved very badly especially on the left side. Behind there were no physical signs. In front, below the left apex the percussion note was slightly higher pitched there was tubular breathing and ægophony was heard extending over the præcordia and invading the right side above the liver The heart was not displaced and there were no signs of aneurysm. No tubercle bacilli were to be found in the very offensive purulent profuse expectoration. During the fortnight that the patient was under medical treatment he improved, and the vomiting which was at first troublesome had ceased and he was on ordinary diet. There was no stridor or dysphagia. The temperature, pulse and respiration had all remained quiet throughout (temperature from 97° to 99 5° F pulse from 112 to 84 and respiration from 36 to 20), and the physical signs had become very much less marked He had just finished a hearty meal when without warning he had a profuse hæmoptysis, and after a few minutes of intense agony he expired like a drowning man before our eyes.

Necropsy —The post-mortem examination revealed a gumma as large as half a Tangerine orange lying between the trachea and the aortic arch. This had eroded on the one hand into the trachea with an aperture two inches in length having warty margins, and on the other hand into the aorta by a pinhead aperture while the heart of the gumma was septic and sloughing The aorta was otherwise quite healthy The lungs on the right side were healthy but on the left above the heart there were several (? six) patches of carnification as large as sparrow's or thrush's eggs. The apices were healthy and there was no sign of phthisis. The Clinical Research Association reported that the mediastinal gumma was quite caseous and necrosed and showed no microscopic features The carnified lung showed pneumonic consolidation as well as much interstitial fibrosis. There are also foci of small cells not unlike gummata but with no caseation. There are no signs of tubercle or malignant growth "

Remarks —The fact that a gumma may establish communication between the trachea and aorta is mentioned in Dr Hector Mackenzie's article on Syphilis in Gibson's Textbook on Medicine but it is presumably very uncommon. The evidence that the lung in this case was affected with syphilis is strong if not absolutely convincing The points in favour are (1) that tubercle can be excluded by the healthiness of the apices the absence of pyrexia and the microscopic appearance of the lung and sputum (2) that a patchy septic pneumonia can be excluded by the absence of pyrexia and the presence of fibrosis in the lung (3) that gummata were present in the mediastinum and chest wall, (4) the presence of fibrosis and of foci of small cells not unlike gummata in association with broncho pneumonia (5) the size and number of the nodules and their situation in the middle of one lung and (6) the purulent offensive sputum without pyrexia The points *against* the diagnosis of pulmonary syphilis are (1) its extreme rarity (it is said that there are less than a dozen undoubted museum specimens in London) (2) the failure of potassium iodide (for a short time) and (3) the fact that the carnified nodules were red and not caseous or greyish white. This may be accounted for by the nodules not having yet reached the stage of caseation.

Medical Societies

BRITISH GYNÆCOLOGICAL SOCIETY —A meeting of this society was held on July 10th, Dr Heywood Smith a vice president being in the chair —Dr F A. Purcell showed (1) three Uteri removed by vaginal hysterectomy two for malignant disease and one after perforation of the fundus during dilatation for the purpose of removing the sloughing particle of a fibrous polypus previously expelled and (2) a Uterus with Multiple Myomata removed through the abdomen.—These specimens were discussed by the Chairman Dr Routh, Dr J J Macan Dr Macnaughton Jones and Dr H Snow —In his reply Dr Purcell agreed with Dr Routh that hard and tender vaginal carunculæ suggested malignant disease. In the case of perforation the dilatation had been quite gradual commencing with No 1 Hegar and it was No. 9 that had perforated the fundus Experience had taught that no serious results need necessarily follow perforation but for it to be harmless the instrument should be aseptic and the endometrium also and as the pedicle was sloughing he removed the uterus He quite approved of preliminary dilatation by a tent. Professor Bossi's instrument, which Dr Macnaughton Jones had shown them, might perhaps have been used in the case without accident.—Dr Macnaughton-Jones read notes of a case of Suppurating Ovarian Cystoma complicating miscarriage during the third month. When he was consulted 14 days after the miscarriage there were signs of extensive cellulitis and some peritonitis, a week later there were softening and fluctuation in the vaginal vault. On the twenty third day after delivery and the eleventh of the illness, after exploration, as the abscess could not be satisfactorily reached by the vagina, cœliotomy was performed A cyst extending nearly up to the umbilicus, with wide adhesions which bled freely when separated, burst during manipulation and pus escaped, the peritoneal cavity was flushed out with formalin solution Alarming symptoms supervened on the fourth day but the patient rallied and from the fourteenth day her temperature was hardly above normal and she did well—In reply to Dr Snow, Dr Macnaughton-Jones said that the strength of the formalin solution was 1 in 5000, but he had frequently employed it in the peritoneal cavity in solutions of 1 in 3000 and even of 1 in 2000, and never with bad effect.—Dr H M Macnaughton-Jones, jun, for Dr R. D Purefoy, Master of the Rotunda Hospital, Dublin, read (1) notes of a case of Cystic Ovaries and Rudimentary Uterus without any Vagina (the patient was tall and well developed with normal mammæ and external genitals, and had sought relief for molimina associated with incapacitating pain), and (2) notes on a Pedunculated Secondary Growth from an Abdominal Cicatrix after hysterectomy (the operation had been done for a benign tumour) Dr Purefoy had not heard of such growths after hysterectomy, but they were described by Bland Sutton as occurring after ovariotomy and one such had come under his notice.—Dr R H. Hodgson read a paper on a case of Double Pyosalpinx removed after 17 years' suffering

---

[1] Wilson Fox: Diseases of the Lungs and Pleura, p 942.

WIGAN MEDICAL SOCIETY—A meeting of this society was held in the board room of the Royal Albert Edward Infirmary on July 15th, Mr T M Angior, the President, being in the chair The President was elected to represent the society at the International Congress of Medicine to be held at Madrid in April, 1903 The following cases were exhibited by Dr R. Prosser White (1) Lupus Vulgaris treated by Injections of Old Tuberculin (a complete cure), (2) Keloid of the Cheek after a Burn, (3) Lupus Erythematosus treated by the New Tuberculin (cure), and (4) other cases of Tubercular Affections of the Skin.—Mr Hugh E Jones exhibited (1) Miscellaneous Drawings Photographs, and Radiographs (the latter by Mr C Thurstan Holland) illustrating the Effects of Concussion of the Eyeball Gunshot Wounds of the Orbit, &c., (2) Patients illustrating Vairous Forms of Cataract and their Treatment, (3) Plastic Operations for Contracted Socket and Cicatricial Ectropion, and (4) Ophthalmoscopic Cases—Mr W Berry showed the following cases in the wards 1. A patient who had aborted two months before admission A portion of placenta was supposed to be retained as there were repeated hæmorrhages He curetted and in place of placental tissue omentum was pulled down through the cervix, a piece four inches square was ligatured and cut off, the remaining portion was pushed back through the cervix, and the uterus was plugged with iodoform gauze. This was allowed to remain for 48 hours and afterwards she was douched daily She made an uninterrupted recovery 2 A case of Double Genu Valgum in a girl, aged 15 years Macewen's operation was performed on both thighs at the same time with an excellent result and without a single rise of temperature 3. A case of Concussion of the Brain 4 A large Gluteal Abscess in a female.—Mr C M Brady showed a case of a Cyst in the Right Spermatic Cord of a boy, aged one and a half years—Dr J Blair showed a large Papilloma of the Vagina in a girl, aged one and a half years—A vote of thanks to the board of management of the infirmary concluded the business

VACCINATION EXPENDITURE—Several of the boards of guardians in the west of England have been recently discussing the resolutions passed at a conference of delegates from the metropolitan boards of guardians to the effect that fees for primary and revaccination cases should not exceed 2*s* if performed at the home of the patient and 1*s* 6*d* if performed at the surgery of the public vaccinator The resolution at present has not received much local support, some of the guardians referring the matter to a medical committee, as the Newton Abbot board did on July 23rd. The Falmouth and Stonehouse boards of guardians at their meeting held on July 24th were both in favour of the proposal, whereas the South Molton guardians, who also held their meeting on the same day, would not entertain the idea.

Reviews and Notices of Books.

The Mental State of Hystericals By PIERRE JANET, M.D. With a Preface by the late Professor J M CHARCOT. Translated by C R. CORSON London and New York: G P Putnam's Sons 1901 Pp 535 Price 15*s* net.

Dr Pierre Janet has long been known as one of the ablest clinical and psychological investigators among the many brilliant pupils who owed their inspiration to the late Professor Charcot, and the book before us is an excellent example of temperate and judicious examination of a most difficult subject. The author's conception of hysteria is broad and philosophical. Hysteria is viewed as a neurosis which affects the entire personality of the individual, disturbing not only the psychical functions and thus giving rise to a protean assemblage of mental symptoms but modifying also the bodily functions and bringing about various visceral and somatic troubles

The work is divided into two parts The first part occupies about 200 pages and deals with the so called "mental stigmata" of hysteria. The various symptoms and conditions studied here include the anæsthesias of hysterical patients, the forms of amnesia from which they suffer, the disorders, or rather the defects, of will which they exhibit (aboulias), the motor disturbances which they manifest, and, finally, the modifications of character and disposition which they undergo Under each of these headings a vast amount of facts and observations is collected and discussed and the pathological basis and significance of the conditions are clearly pointed out. Full references are given to original memoirs and articles The second part of the work occupies nearly 300 pages It contains the most illuminating description and discussion to be met with in medical literature on such subjects as suggestion and sub conscious acts, fixed ideas among the hysterical, hysterical convulsions, and the conditions of delirium, delusion, and somnambulism which are present in the graver forms of hysteria. Among so much that is excellent it is difficult to pick out any particular part of the work for special mention, but the chapter on Suggestion and Sub conscious Acts may be referred to for the clearness of exposition, depth of insight, and abundance of clinical and psychological knowledge which it exhibits The work is one that deserves to be consulted and studied carefully in view of the light which it throws on the various clinical and psychological aspects of hysteria. It will for long remain the classical work on the subject. The translation is executed with great felicity and clearness of expression and the text is remarkably free from errors

Transactions of the Ophthalmological Society of the United Kingdom Vol XXI, Session 1900–1901 London J and A. Churchill 1901 8vo, pp 328 Price 12*s* 6*d*

THE publication of a volume of Transactions, annually or periodically, by such a society as this is of considerable importance The longer papers read before the society would no doubt be reproduced by the authors in another form but the memory of a large number of cases, or of what are now called "card specimens," would in all probability be utterly lost even if they gained admission into the pages of the more prominent journals devoted to general medicine and surgery Appearing in the Transactions of a society easy reference can be made to them and the wearisome process of looking through many pages of indices dealing with irrelevant subjects is saved Moreover, the comments of experts are often appended and the experience of others as well as that of the authors is thus obtained

The arrangement of the contents of the volume before us is topographical, diseases of the conjunctiva, the cornea, the iris, and the choroid and the retina brought before the society being successively given Other sections are devoted to injuries of the eye, operations instruments and appliances congenital conditions colour blindness, and ophthalmic pathology There are no less than 18 plates, many of them being well executed chromo-lithographs, whilst others illustrate pathological specimens the microscopical features of which are reproduced by photography There are also many diagrams and drawings in the text.

There is a good article by Mr Norman G Bennett, in which the author adduces evidence showing the frequent co-existence of lamellar cataract and hypoplastic teeth—that is to say teeth presenting imperfect calcification—and considers that this combination suggests a common cause for the two lesions The ocular lesion, however he points out differs from the dental lesion in being produced after the development of the tissue instead of during that process as it must be in the case of a calcified tissue. He is inclined to think that of several causes capable of producing hypoplastic teeth one or more only can cause the ocular lesion. He maintains that lamellar cataract is a disease of early infantile life and is due to some general derangement of health which also affects the teeth. The general derangement is brought about by errors of feeding and nutrition.

Various forms of apparatus and new instruments are described. Thus Mr A. Ainslie Hudson extols the action of an instrument adapted to effect vibration massage It is worked by electricity and sets up rapid vibrations the influence of which penetrates to a great depth. He has found its application extremely useful in a case of incessant supra-orbital neuralgia and in cases of paralysis of the external and internal recti Major Herbert E. Drake Brockman I.M.S., has devised a new pattern of eye speculum which amongst other advantages is light and by the introduction of an additional joint in the shanks allows of considerable alteration of the general curve to suit the contour of the face. Mr H Secker Walker has devised a diagrammatic model intended to assist in the teaching of refraction in relation to the eye. Mr Gustavus Hartridge uses a curved capsulotomy knife of which he gives a drawing Mr J H. Tomlinson exhibits a recording colour perimeter and Mr C. S Blair a portable refractometer

A valuable communication illustrated by many plates is that by Dr Leslie Buchanan In this article the pathological changes that occur in the eye as a consequence of the entry of a chip of metal into it are carefully followed out. The microscopical feature of the exudate that is found in cyclitis the multiplication of nuclei and cells, the subsequent processes of fibrosis and fatty degeneration, and the final stage of ossification are all fully described and are well shown in the illustrations Another article of considerable merit and much originality is that by Dr Ernest Thomson on the Determination of the Influence of the Eyeball on the Growth of the Orbit, by Experimental Enucleation of One Eye in Young Animals. Sir Anderson Critchett records some interesting cases of bullet wounds affecting vision received during the late war There are two communications from Dr F W Edridge Green one upon a Trichromic or Three-unit Case of Colour blindness and the other upon the Evolution of the Colour Sense Short accounts are given of a large number of isolated cases occurring in the practice of the members The volume supplies good evidence of the vitality of the society

---

Higher Mathematics for Students of Chemistry and Physics By J W MELLOR, D Sc. London Longmans Green and Co. 1902. Pp. 543. Price 12s 6d

ADVANCED students of theoretical chemistry have long felt the want of a book like this which contains just the kind of mathematics that is required daily in connexion with their work. Scientific investigators are constantly endeavouring to group together their observations under some general law After collecting their facts they proceed to guess at the nature of the underlying law that connects them. Assuming this working hypothesis as provisionally true they argue as to its effect in other cases, and a further appeal to experience either verifies or negatives the truth of the hypothesis. It is only comparatively recently that this last and most important step of verification has been taken with regard to certain chemical theories. This is mainly because chemists as a class are not mathematicians and they do not realise that some knowledge of the calculus would show them exactly what experiments would finally test their hypotheses. Dr Mellor's admirable method of dealing with his subject is well exemplified in his introduction to the study of integration. Cane sugar is converted into invert sugar in the presence of dilute acids. What law governs this change? Wilhelmy has suggested the law that the speed of the chemical reaction at any moment will be proportional to the amount of cane sugar actually present in the solution The law however in this form cannot be experimentally verified for the speed is not really constant during any finite interval of time because the amount of cane sugar remaining to be acted on is continually decreasing The law is therefore expressed as a differential equation and then by the methods of integration the amount of invert sugar formed according to this law in a given time whether five seconds or an hour can be found. On making these experiments the results are in complete accordance with Wilhelmy's hypothesis which is now known as Wilhelmy's law Integration therefore bridges the gap between theory and fact in a form suitable for experimental verification This simple instance will show that some knowledge of both differential and integral calculus is required by the scientific investigator of chemical laws.

The last chapter of the book contains a very complete discussion on the Theory of Errors. It is most important that all scientific workers in the laboratory should know how to interpret their observations. If for instance, 13 different observations of the atomic weight of oxygen are made the method of finding the best representative value for this set of observations is given, and further if any observation is very discordant with the others whether it should be rejected or not. When a very large number of observations have been made no one should be rejected under the pretence that it vitiates the other observations when however the number is small the abnormal measurement if allowed to remain, would exercise a disproportionate influence on the mean. In these circumstances Chauvenet's criterion is recommended which is an attempt to show that trustworthy observations will not deviate from the arithmetical mean beyond certain limits

Enough has been said to show the eminently practical nature of the book the able chapter on Fourier's theorem would probably not satisfy a pure mathematician but the two assumptions made in it are clearly stated and those who have waded through the elaborate investigations to justify them will be the first to admit that they have no place in a book of this kind. The style of the book is clear and interesting and the type is excellent and remarkably free from misprints. A minus sign should be substituted for the plus sign on page 27 (12) and on page 30 in example (5) a *x* should be substituted for the *y* One misprint occurs several times parellelopiped for *parallelepiped* It may be noted too that in the section on Solid Geometry the positive direction of the axis OY is taken outwards whereas this is usually taken as the negative direction The author is to be sincerely congratulated on his masterly treatment of such a large range of subjects, each section of which is of more or less practical importance to those engaged in chemistry or physics

---

Le Traitement Médical des Inflammations du Cæcum—Typhlite, Pérityphlite, Appendicite (*The Medical Treatment of Inflammations of the Cæcum—Typhlitis, Perityphlitis, Appendicitis*) By Dr BOURGET, Professor of Clinical Medicine in the Faculty of Medicine of Lausanne, Switzerland. Geneva C Eggimann and Co

THIS is a very useful practical book—especially useful just now, for it is evident from the correspondence columns of THE LANCET that medical opinion and practice in relation to the questions treated are not yet mature. Thoughtful physicians, especially those in charge of patients in the wards of hospitals, have long been face to face with the difficulties. They have frequently had under their care patients who have presented the classical signs of perityphlitis—pain on pressure over the situation of the cæcum, resistance felt over this area, sometimes a localisation of the maximum of the tenderness and pain over the anatomical site of the appendix vermiformis together with subjective signs suggesting a local peritonitis In many cases they have found rest and careful treatment to be followed by recovery In some cases there has been relapse, but even in relapsed cases recovery has followed The relative proportions of recoveries to deaths have been variously estimated. Some have thought that the great majority of patients have recovered, others have put down the fatal cases as one quarter at least of all those observed. It has been, at any rate, proved that in a very notable proportion surgical interference has in these later days been a means of saving life. It is easy for the reasoning to be in favour of surgical intervention in *all* cases This seems to be illogical in view of the fact—if it is a fact—that a large number of patients recover without the intervention of the operating surgeon. This little book, certainly without any elaborate and profound reasoning, takes the side of the *medical* observer, agrees that a very large proportion can be cured by judicious treatment without surgical operation, and points out the practical means to be adopted. First the author dismisses the treatment by external applications of ice and by internal administrations of opium as useless or worse than useless. He insists upon the value of prophylactic measures, affirming that all the individuals attacked with perityphlitis suffer from gastro-intestinal troubles Anti-dyspeptic treatment is therefore of high importance, and the chief of these means is anti constipation treatment by diet, by the administration of vegetable juices, by judicious muscular exercises, and by laxatives such as Carlsbad salts or capsules containing small doses of castor oil. A suitable *régime*, too long to quote here, is given on page 23 If an acute crisis occurs the diet should be liquid, castor oil in sufficient doses, with salacetol in doses of from 15 to 30 grains, should be given and enemata should be administered. This is the strong contention of the author that any preconceived objections to intestinal lavage in these cases are chimerical and that by means of a suitable apparatus a litre of warm water with ichthyol (four parts per 1000 in an aqueous solution) and a little olive oil should be gently injected as an enema twice a day The author claims for these oil containing enemata that they rapidly calm the pain and distress, producing an effect analogous to that observed in hepatic colic when olive oil has been ingested. After the second or third day of such treatment the castor oil taken by the mouth as an aperient is omitted and replaced by a saline laxative containing phosphate and sulphate of soda. The enemata are continued for from two to 10 days By this treatment it is possible that the necessity for operative interference will be much reduced though not abolished It is illogical to [illegible] a surgical operation in all cases, and still more illogical to remove the vermiform appendix as a prophylactic measure in the healthy

The author concludes with records of all the cases (23 in number) of perityphlitis which have been under his care in hospital since January, 1901 These deserve careful study and go far to fulfil the indication of a correspondent in THE LANCET of July 19th, p 184, who suggests that it would be well for physicians instead of recording the antiquity of the disease, to enlighten the medical mind as to the mode of treatment found by them to be most successful.

LIBRARY TABLE

Heresies, or Agnostic Theism, Ethics Sociology, and Metaphysics By H CROFT MILLER. Vol V London Grant Richards 1902. Pp 599 Price 10*s*—In the preface of this volume which is the fifth of a series, the author gives a brief history of his life, which he tells us may be divided into three periods During the first or blind and trusting period "he faithfully fulfilled one day per week what passes as the Christian duty of mumbling responses and pretending to listen to pulpit orations." During the second or inquiring period "he worshipped at the altars of empirical science" and he also "slashed at metaphysic" At this time he contributed to free thought journals and wrote a book in which he applied "in the moral and religious arenas" the investigations of a distinguished German biologist. Another book which adumbrated "the author's third personality" was "a pseudo-metaphysical struggle with the materialistic ogre." At length came the wrestling period "Like a nightmare came the dead emptiness of what had afforded the illusion of living substance" He was troubled by "the great secret, the Whence and Whither" He asked himself whether a man could rest with Conservation and Dissipation, Gravitation, Catastrophism, Uniformitarianism, Central Localisation, and Darwinian Descent? "One man at any rate could not", That man was Mr H Croft Miller Then the inner voice told him that what he knew was mind, and that he should learn what is real, but he found a difficulty How could he account for hands, brains, telephones, rivers, dead bodies, time, space, and other things? The inner voice told him to seek "The author has sought, and he believes has found" He reveals what he has found He no longer slashes the metaphysic, on the contrary, he has become the chief teacher, if not the actual discoverer of "the metaphysic," and as he is so good as to explain to us, "this concluding volume of the metaphysic may be said to contain its empirical authentication" He goes on to express the hope that "the metaphysic in its main aspects is now beyond successful intellectual attack." The author, kindly recognising the difficulty that a critic might have "in dealing with a work covering unfamiliar ground," advises us to approach it in the spirit of a scientific investigator A perusal of parts of the present volume may, he thinks, 'whet the appetite for a serious study of the whole work." A study of the four volumes already published may make the reader look forward with respectful joy to another volume which the author promises, which is to deal with morality and religion Mr H. Croft Miller is so kind as specially to recommend the present volume to physicians "The metaphysic" has something to teach them—to wit, that "what is called the advance of medical science constitutes what may be called an advance in the manufacture of disease The more we popularise medical studies of new disease the more we popularise the diseases themselves. What is called preventive medicine operates beneficially by hypnotising the public into confidence, which is another way of saying that it prevents the public from hypnotising the matter soul so as to propagate the disease" Mr Miller is mistaken in suggesting that his book does not deal with familiar subjects.

We have heard of Mrs. Piper the lady who picks at her finger nails, and of Mrs Eddy of Christian Science, of Home, who floated in the air we have also heard nor have we forgotten Katie King Mr Miller recalls the doings of some of these worthies. His quotations are historically interesting his own statements will be thought by some people blasphemous, by others absurd. The book is more amusing than dangerous but considered as a work of humour it is dear at the price charged for it.

Some Thoughts on the Principles of Local Treatment in Diseases of the Upper Air-passages Being Two Lectures delivered at the Medical Graduates' College and Polyclinic on Oct. 2nd and 9th 1901. With an Appendix consisting of Two Letters published on Nov 23rd, 1901, and on Jan 11th, 1902, in the *British Medical Journal*. By Sir FELIX SEMON M D Berlin F R C P Lond Physician Extraordinary to the King, Royal Prussian Professor of Medicine, Physician for Diseases of the Throat to the National Hospital for the Paralysed and Epileptic, Queen square. London Macmillan and Co Limited New York The Macmillan Company 1902. Pp 130 Price 2*s* 6*d*. net.—What might be called the text of these lectures was Dr J F Goodhart s statement that throats and noses suffer terribly from this lust of operation that has beset the public, though Sir Felix Semon para phrases this in his ' thoughts" and says that has beset the rhinologist. We must, however, state that it is not at the English rhinologist alone that this odium is hurled but also at numerous exponents of rhinology in Germany The author refers early in his lectures to the well known tendency of medical men to rush from one extreme to the other, to praise a treatment beyond its merits or to condemn it entirely without due cause. Speaking generally our old friend ' placebo" is ruthlessly condemned as an instance of want of strength of mind on the part of a medical man These lectures are extremely well prepared well written and give evidence of an absolutely thorough acquaintance with the literature of the speciality Possibly they are more destructive than creative theories and practices are attacked but there is given in place little but general broad lines of guidance. There is no doubt that the author shows wisdom for had he attempted a wider definition he would have laid himself open to a task which he could not have completed within the limits of time at his disposal when the lectures were delivered The letters which are inserted are two, the first and last of a controversy which was carried on in the pages of our contemporaries

The Neuroses of the Genito-urinary System in the Male with Sterility and Impotence By Dr R. ULTZMANN Professor of Genito-urinary Diseases in the University of Vienna. Second edition, revised by the translator GARDNER W ALLEN M.D Surgeon in the Genito-urinary Department of the Dispensary of Boston Philadelphia F A. Davis and Co 1902. Pp. 198. Price $1 —We can find little to praise in either the matter of this book or its manner Professor Ultzmann did not live to revise his own work and it is doubtful whether such an undertaking was required of any body else. Those who take a pleasure in the freest use of barbarous pseudo-scientific terms and in the perusal of masturbatory consequences will be satisfied in these pages—other persons will not peruse them. The translator is we imagine, chiefly to blame for the unattractive nature of the work as it appears in English

---

JOURNALS.

The Practitioner —The July number of the *Practitioner* contains an excellent practical article upon the Operative Treatment of Malignant Disease of the Uterus from the pen of Dr Walter W H. Tate. Dr Tate lays stress upon the frequency with which an accurate diagnosis can only be made by the aid of examination under anæsthetics and points out that the decision for or against operation depends upon this examination. He remarks that cases which appear to be favourable for operation often prove, under the more searching examination possible with anæsthesia, to be really unsuitable for any such treatment. The question of vaginal hysterectomy is described in close detail and the mortality of it is stated as not more than 3 per cent. Mr A. G R. Foulerton contributes a long article upon the Causation of Carcinoma and Sarcoma. The various prevalent ideas and innumerable authorities are quoted Conclusions are reserved for a future number The editor falls foul of Mr Jonathan Hutchinson s remarks upon the possible rôle of arsenic in the causation of cancer

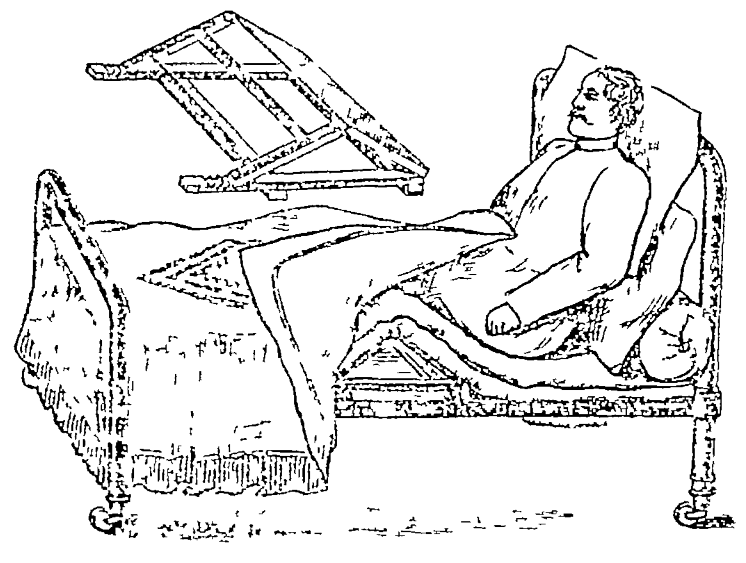
Annals of Ophthalmology Managing Editor, H. V WÜRDEMANN M D Vol XI. No. 2. April, 1902. Pp 239 Published quarterly price 18*s* per annum.—The American journal, *Annals of Ophthalmology* besides con taining good original articles is conspicuous for the excellent abstracts of contemporary ophthalmological literature embracing not only the work done in France, Germany, Holland, and Italy but that which has been published in Russia, Scandinavia, Hungary and Japan. The chief original articles in this number are as follows. Glaucoma, by Dr Edward B Coburn whose efforts to ascertain the etiology of the disease consisted in undertaking four series of experiments the first of which was devoted to the determination of the course of the lymph currents in the anterior segment of the eye the second to the effect of increased pressure in the anterior and posterior chambers, the third to the results of the introduction of foreign material into the eye, and the last to the effects of the indirect introduction of substances through the circulation and the closure of the channels of exit by causing changes in the ciliary region and aqueous. Dr Coburn finds that intra-ocular changes may be induced by deleterious substances in the circulation and *shows* that these changes are associated with narrowing of the angle between the iris and the cornea. Dr Howard F Hansell and Dr Harry Friedenwald also deal with the subject of glaucoma. Dr E F Snydacker discusses Professor Mauthner s method of diagnosing paralysis of the depressors or the elevators of the eye. Dr J P Nuel, the professor of ophthalmology in the University of Liége, and Dr F W Marlow professor of ophthalmology in the University of Syracuse, N Y supply the abstract of a Report on the Toxic Amblyopias, including quinine, tobacco alcohol and other forms of amblyopia. They show that the nerve fibres are primarily affected and that secondarily proliferation of the interstitial tissues takes place. Lastly, Dr Frederick Herman Verhoeff of Boston offers a Theory of Binocular Perspective with some remarks upon torsion of the eyes, the theory of the vicarious fovea, and the relation of con vergence to the perception of relief and distance

The Journal of Physiology Edited by Sir MICHAEL FOSTER, K.C.B. F R S. and J N LANGLEY, Sc.D F R.S. Vol XXVIII No 4. London C J Clay and Sons July 21st, 1902. Pp. 67 Price 4*s*.—The articles contained in this part are six in number and are as follows — 1. Dr Francis W Goodbody Dr Noel D Bardswell and Mr. J E. Chapman On Metabolism on Ordinary and Forced Diets in Normal Individuals. The experiments conducted by these observers show that an excessive diet is followed by lasting bad effects that except when extreme forced feeding is employed very little nitrogen is retained in the system, that the quantity of urine of high specific gravity is augmented and that the greatly increased quantity of nitrogen eliminated by the urine is not in the form of urea, uric acid, or ammonia. Nor was there any great increase of nitrogen in the fæces there was a great increase in the quantity of fat in the fæces With forced feeding the body-weight rapidly increased On this feeding being discontinued a rapid decrease of the body weight took place 2 W M Bayliss Further Researches on Antidromic Nerve Impulses. In addition to other conclusions which the writer of this article draws from his experiments he finds that there are no vaso-dilator fibres to the hind limb in the abdominal sympathetic chain and that there are no vaso-dilator fibres supplying the small intestine in the vagus nerve, but that such fibres are present in the posterior roots of the twelfth and thirteenth thoracic nerves 3 Sir W R. Gowers Taste and the Fifth Nerve The importance on clinical grounds of the petrosal and vidian nerves and of the spheno palatine and otic ganglia is dwelt upon in this communication, and it is pointed out that impairment of taste does not follow disease of the facial nerve in the skull or of the roots of the glosso-pharyngeal nerve 4 Mr O H. Fagge describes the innervation of the urinary passages in the dog He finds that the nerve supply to the primitive urinary ducts and to all the passages developed from the Wolffian ducts and their outgrowths, including the uterus and vagina, is derived from the sympathetic system through the hypogastric nerves On the other hand the innervation of the bladder derived from the urachus is furnished, probably later in the course of evolution, directly from the sacral portion of the spinal cord along the pelvic visceral nerves 5 Dr Charles S Myers gives the results of his observations on the visual acuity of the natives of Sarawak and finds their acuity of vision to be about one and a half times greater than the normal degree 6 Mr M Siegfried describes a new albuminoid obtained with gelatin from white connective tissue to which he has given the name of "reticulin" This number of the *Journal of Physiology* also contains the Proceedings of the Physiological Society at the meeting of July 5th, 1902.

New Inventions.

A NEW BED REST

I SEND you a sketch of a bed rest which I have devised for the purpose of keeping a patient permanently "propped-up' in the bed The difficulty of keeping anyone in this position for any length of time is well known to the medical profession and still more so to the nurses A heavy and helpless patient has to be dragged up in the bed repeatedly, both for his own comfort and it may be for vital reasons, and the tax on the strength of the nurses, to say nothing of the patient, is enormous, for it must be remembered that the heavier the patient the more rapidly he settles down in the bed, despite all the appliances hitherto used



The sketch, I think, speaks for itself, but it may be mentioned that the apparatus is intended to be placed *beneath* the mattress and that the part which supports the backs of the thighs is made of wire to give spring and therefore, comfort When placed in position this contrivance converts *any* bed practically into a Bombay lounge. Its various uses will at once occur to anyone, in fact, in every case where a bed rest has hitherto been ordered and has after a few hours' trial been discarded as useless, its convenience will be experienced Personally, I have never known a bed rest to be used for more than a day, but I have seen the above invention used for seven weeks continually in a very severe case of rheumatic fever with pericarditis and endocarditis, and as my patient has recovered with an absolutely sound heart (which fact I believe to be due to the constantly raised position) I can with a certain confidence recommend it to the profession generally In conclusion, I have to say that the bed rest is called the "Sister Doris" and that it is made by Messrs Allen and Hanbury of Wigmore street, London, W

FROM

THE LANCET, *SATURDAY, JULY 31*, 1824.

ROYAL ACADEMY OF MEDICINE.

Sitting of the 11*th of March*

M. BECLARD presented to the Academy, in the name of M.M DUBOIS and BELLIVIER, a fœtus which had remained seven years in the womb of the mother It was contained in a bag situated on the left side of the uterus. It appeared to be transformed into a kind of adipose substance, resembling the fat of dead persons

Sitting of the 25*th of March*

M M RICHERAND and JULES CLOQUET exhibited one of the patients from the hospital St. Louis, whose inferior extremities could be lengthened or shortened, when the man liked, to the extent of three or four inches From several pathologico-anatomical observations, it was judged that this affection arose from a destruction of the heads of the thigh bones, and from erosion of the parietes of the cotyloid cavities The patient is fifty years of age, walks with extreme difficulty, but without pain Whilst resting the body on either limb, it becomes shortened, and the trochanter major touches the crista of the ilium , but when, on the contrary, he raises it, it elongates and returns to its natural size. In this same patient there are several exostoses in different parts of the pelvis, and numerous large osseous tumours in the substance of the muscles

HYDROPHOBIA —We regret that in none of the numerous instances of hydrophobia which have lately occurred in this country, has the plan so strenuously recommended by M MAGENDIE, (injection of water into the veins) been tried The ordinary remedies, such as blood letting, opium, &c so seldom afford any relief in this dreadful disease, that we are surprised that a mode of treatment so simple as M MAGENDIE'S, and which holds out a chance of cure has not received a fair and impartial trial. From the publicity which M MAGENDIE'S case received, there can scarcely be a professional man in the country who is not acquainted with it, and we therefore entreat medical men to try the injection of water into the veins in any case of hydrophobia which may come under their notice Some blood ought to be abstracted from the arm previously to the injection of the water, and the water should be injected in a luke warm state

The British Medical Association The President's Address

IN bidding the British Medical Association welcome to the town in which it holds its annual meeting the President for the year usually finds an interesting topic for his opening address in the medical history of the locality acting as host to the Association Mr WALTER WHITEHEAD has done so this year and in Manchester he had a fertile and suggestive subject ready to his hand. The history of Manchester is for the most part modern history It is the history of a city bound up in the minds of men with the progress of modern manufacture modern commerce, and modern political opinion In political history Manchester is closely associated with the great struggle for financial and fiscal reform that marked the early part of the last century, and it is interesting to note that its right to Parliamentary representation dates only from 1832, the year in which the British Medical Association now its guest, was founded Before the Reform Act in that year did away with a state of things which to us, only 70 years after seems almost beyond belief the appearance of Manchester in the House of Commons had been restricted to the presence of two Members in CROMWELL'S Parliament of 1654 one of whom, CHARLES WORSLEY carried out the Protector's celebrated mandate to 'Remove that bauble We need hardly say that during the time preceding the great Reform Act Manchester was already a huge commercial centre while pocket boroughs with a dozen voters were returning Members to Parliament With the general and political history of Manchester Mr WHITEHEAD'S address naturally did not deal nor need we do more than remind our readers of the part played by Manchester politicians in developing the greatness and securing the liberty of which the nation is justly proud But we think that such a reminder is called for as without doubt the progress of medicine and civil arts has followed hard on the increased political freedom in the securing of which the politicians of the Manchester school played so vigorous a part.

The city which is associated with the names of COBDEN and BRIGHT and therefore with the preaching and practice of doctrines of peace, retrenchment, and political freedom, was not likely to be behindhand where scientific progress was concerned and where the physical welfare of a large and industrious population was also involved. In such circumstances we find without surprise that the Royal Infirmary at Manchester had its origin so far back as in the middle of the eighteenth century and that it is reckoned to be one of the oldest—possibly the oldest—of all Manchester's great public institutions It owed its foundation to the generosity and public spirit of two gentlemen named CHARLES WHITE and JOSEPH BANCROFT but soon the small house that they had fitted up proved too small; but the importance of their enterprise was appreciated by the community so that three years later in 1755, a wing was added which provided beds for 40 patients and other additions followed in due course Mr CHARLES WHITE, who was the first surgeon associated with the Infirmary, had begun his career in London and was a friend and fellow student of JOHN HUNTER. It was more than half a century later when the need for a medical school at Manchester was supplied through the energy of Mr THOMAS TURNER, who appears from Mr WHITEHEAD'S address thus to have founded the first great provincial medical school in England and to have done so at the very time at which Manchester was most agitated by the political strife and unrest associated with and exemplified by the outrage of "Peterloo" The history of medical education at Manchester its later connexion with the great modern instrument of general education in that city, the Owens College, and the growth of the importance of the latter through the union with it of the Manchester School of Medicine, can be traced by those who pursue the subject in Mr WHITEHEAD'S address as printed in our column should they not have heard him deliver it at the meeting of the British Medical Association. We must congratulate Mr WHITEHEAD on the completeness with which he has studied the interesting subject.

The most modern development with which Mr WHITEHEAD found himself confronted was no doubt the prospect of Manchester becoming in the near future the home of a university This has been its ambition for more than two and a half centuries. It petitioned the Long Parliament for a charter in 1641 and its petition was opposed successfully by York which city put forward rival claims After the Owens College had established itself upon a firm basis and the advantages had been recognised that are obtained by placing education of a high class within the grasp of those who cannot afford to go far afield to seek it, Manchester again sought a charter for a Manchester University When difficulties arose due again to rival claims of other north country town the Victoria University was founded as a compromise Birmingham has now a separate university and Mr WHITEHEAD observes that a federal university has served its turn and higher education in Manchester has reached a stage when a local university has become not only a necessity but a legitimate one" No Manchester man is likely to dissent from this view though we are not quite sure that the question of the value of local universities has received due attention from people not locally concerned. The excellent work which has been done at the Owens College and the admirable facilities for education existing in Manchester whether for training in medicine and surgery or in those other subjects which should be included in the curriculum of a university are admitted, while the foundation of a Manchester university is a fact almost accomplished.

◆

The British Medical Association The Address in Medicine

THE most valuable feature which reasonably may be looked for in an authoritative address upon any practical subject is a summary of what has been done with regard to that subject in the past and a deduction from this of what ought to be done in the future. Reading the Address in Medicine, which we publish on another page, with some such expectation in our mind, we may well congratulate Sir THOMAS BARLOW upon the manner in which he has demonstrated the recent advances in medicine, and still more upon the emphasis with which he points out the direction in which help is necessary if such advances are to be pushed further in the future. All the world is aware of the strides which surgery has made along the roads which modern science opened to its enterprise Every layman can preach on the changes wrought by the antiseptic principles of Lord LISTER. The advance of medicine, less striking to the ordinary individual though scarcely less radical to the cultivated mind, is apt to be overshadowed by the almost sensational progress of its sister art, and it is well, therefore, that a physician of such practical attainments as Sir THOMAS BARLOW should set himself to demonstrate the benefits which the practice of medicine reaps, and is still likely to reap, from the acquisition and application of scientific knowledge Sir THOMAS BARLOW takes as his text the thesis that "the advances in the treatment of disease have been real and satisfactory in proportion as they have been harmonious with the complete knowledge of the natural history of disease." The diseases with which he illustrates his contention are well chosen. First comes diphtheria—a complaint in which, perhaps more than in any other equally formidable, the modern science of bacteriology has rendered possible an accuracy in diagnosis and an efficiency in treatment that were wanting in all the sagacity and all the insight which a less instructed generation of practitioners was able to bring into play Bacteriological examination renders an early and positive diagnosis frequently possible, and the antitoxin treatment provides us with a remedy which, if opportunely employed, enormously reduces the fatality of diphtheria and is harmless when exercised upon doubtful cases where its use is not actively beneficial. Moreover, as Sir THOMAS BARLOW points out, in the case of diphtheria, as in other instances, a scientific knowledge of the true cause of the disease and of the manner in which it acts enables us to dispense with vigorous measures suggested by a tentative empiricism—measures which in the case of diphtheria took the form of strong local applications and were not only needless but often productive of real harm. As further examples of diseases in which scientific investigations have rendered specific remedies or adequate preventive measures either accomplished facts or matters of the highest probability Sir THOMAS BARLOW instanced rabies, small-pox, cholera, plague, and typhoid fever Later in his address he alluded to malaria and to tuberculosis. When such a list of formidable diseases is contemplated, and when the difference is appreciated between the doubtful manner in which their arrest was attempted by our predecessors and the precise manner in which this aim is to-day to a great extent attained, the most sceptical of medical men may well feel the fires of hope burning within his breast. When he touched upon nervous disorders Sir THOMAS BARLOW probably put his finger upon the inevitable counterpoise which for ever weighs on the other side against the rising scale of general freedom from disease. Medicine is engaged upon an endless combat with endless foes One disease is banished from our midst, hydra like another dread disorder rises in its place. To-day it seems as though while sanitation and bacteriology were defeating the enemies which preyed upon lung and alimentary canal the ranks of disease are to be recruited from foes whose stress falls chiefly upon the brain and upon the spinal cord. That the fight against this ever-renewed army of diseases may be vigorously and successfully carried on we need the well filled ranks of medical men whose training fits them with every weapon which science and experience have forged. Money and endeavour, private and municipal, must be forthcoming to train these soldiers and we most heartily commend to the attention of our readers the concluding portion of Sir THOMAS BARLOW'S address in which he lays stress upo need for these assistances

The Medical Officer of the Ballachulish Slate Quarries

A DISPUTE involving questions of great interest to a considerable section of the medical profession has arisen at the Ballachulish slate quarries in the West of Scotland. These quarries occupy a remote position on the sea coast of Argyllshire, an extensive county, mountainous in every part and possessing but few towns, the largest of which, Campbeltown and Dunoon, have each of them populations barely exceeding 10,000 About two years ago the Ballachulish Slate Quarries Company, which employs about 400 men, appointed Dr LACHLAN GRANT as the medical officer to the company on an agreement one of the clauses of which was to the effect that the appointment might terminate with a month's notice on either side. Dr GRANT seems to have been well liked by the quarrymen and everything appears to have gone well, so that much surprise and indignation were expressed when it became known in the neighbourhood on July 5th that the medical officer was dismissed from the service of the company without any reason being alleged or any explanation being given

The sequel, as related in the columns of the *Glasgow Herald*, the *Oban Telegraph*, and the *Highland News*, abundantly showed the esteem in which Dr GRANT was held in the district A petition for retaining his services was at once drawn up and largely signed, and a mass meeting of the men, presided over by Dr W DUNLOP ANDERSON of Ardsheal, a retired medical man and a landowner in the immediate neighbourhood, was held on July 8th At this meeting resolutions were unanimously passed expressing entire confidence in Dr GRANT and regret at the action of the directors of the company, also requesting them to reinstate Dr GRANT and urging the desirability of giving the men a voice in the election or dismissal of the medical officer These resolutions and the petitions were at once forwarded to Mr BRUCE LOW, 43, York place, Edinburgh, the company's secretary The directors met on July 11th and on July 14th it was made known that they had confirmed their former decision, thereby disregarding the petition from Ballachulish. On July 15th a second very enthusiastic mass meeting of the men was held. Dr ANDERSON, who again presided, expressed his regret at the action of the company and advised the men to reconstitute their medical committee which already existed and had been consulted by the company with regard to Dr GRANT'S appointment but not with regard to his dismissal. A medical committee of nine members was accordingly elected and the following resolution was passed a copy being at the same time sent to the company s secretary —

> The medical committee unanimously elected at a mass meeting of the employés of the Slate Quarry Company on July 15th, 1902, having learned with deep regret and surprise that the petition signed by over 400 names and the resolution of the employés in favour of Dr Grant has been ignored by the directors and that they still insist in terminating his agreement do hereby reserve to ourselves the right of appointing our own medical officer and hereby give notice, on behalf of the employés that we will allow no deductions to be made from our wages on behalf of any doctor not appointed by us.

This brings the legal aspect of the case into prominence. The directors who we are ready to believe, have acted in complete good faith but upon faulty information have no doubt, had the law on their side up to now , but everyone knows what changes of feature objects and occurrences may undergo according to the light that is thrown on them. The possibility of a fresh complication is suggested by the fact that Dr GRANT is described in the Medical Directory as being not only medical officer to the slate quarry but also Poor law medical officer of the locality Dr GRANT S agreement with the company contained the usual proviso that after quitting its service he should not practi o in the neighbourhood but Dr GRANT is now a public officer bound to practise in the neighbourhood in discharge of his official duties Will Dr GRANT be able to reconcile his obligations to the slate company with his obligations to the poor of the parish ? The point is one that he will soon have to decide and for our part we think that if the parish council wishes him to continue in office as its Poor law medical officer he will be morally right in continuing the discharge of his duties as such.

There is another aspect of the case which the community should not lose sight of and which should be brought at once if it has not been already before the directors of the slate company If Dr GRANT goes in such circumstances as those which we have narrated his successor will be hard to come by It will be our duty to warn medical men against accepting the appointment of medical officer to the Ballachulish slate quarries until Dr GRANT S dismissal is explained, and as long as the quarries have no medical officer the district will have no Poor law medical officer Of course, if Dr GRANT has forfeited his right to his position the directors are bound to discharge him, but every opportunity should be given him of answering all accusations, otherwise the position of medical officer to the quarries is clearly one that cannot be held with safety by any medical man. For no young medical man should ever take a post where it might be open to a small clique to bring charges against him in such a way as to put the stigma of dismissal on him without his even being heard in his own defence.

NEW SEWAGE WORKS —On July 24th the new sewage works for the city of Wells Somerset, were formally opened by the mayor The septic tank system has been adopted The works are situated about one and a half miles from the town and the estimated cost is about £5000.

Annotations.

"Ne quid nimis"

THE KING S HEALTH

WE are glad to be able to report that the King s health continues to be completely satisfactory In every way he has made and is making good progress. In convalescence after acute illness necessitating a serious surgical operation some unforeseen accident may always occur But the King has the best safeguards against any such unfortunate event in the unremitting attention of his medical attendants and in his own virtues as a brave and docile patient. In view of presentiments and rumours that were rife in London at the beginning of the week, and which though quite vague seem to have produced a strong impression in many quarters, we take this opportunity of stating that there need be no apprehension as to His Majesty s ability to go through the Coronation ceremony on the appointed date.

LORD KITCHENER'S DESPATCH

THE publication on July 29th last of Lord Kitchener's despatch on the South African war may be regarded as the last and concluding one of the series. The campaign has been very remarkable in many ways and it has been conducted under so many new and such exceptional conditions as to be unique in the annals of military warfare. If South Africa has been the birthplace of many reputations it has also been the graveyard of some that had been already made. Such are however and must always continue to be the fortunes of war As Lord Kitchener takes care to point out, it may be that notwithstanding all his circumspection the names of some may be omitted from his despatch who have rendered equal or even better service than those who have been mentioned. As regards the medical department it would be difficult to estimate the comprehensive, responsible, and laborious nature of its task. Taken as a whole and compared with other branches of the service can anyone deny that its work has been admirably done and that the officers of the Royal Army Medical Corps, those of the Colonial corps the civil surgeons, and, indeed, all who participated in the care of the sick and wounded throughout this long and arduous campaign are not well deserving of national gratitude and reward? This is not, however the time, nor is there really any need, to vindicate the conduct of the medical services or to point out that the medical officers in South Africa were not, and could not justly be held to be, responsible for the occurrence of diseases arising out of conditions in which they found themselves placed and over which they had no sort of control. Surgeon General Sir W D Wilson M B K C M G —as our readers are aware—has throughout the war as the principal medical officer borne a great weight of responsibility By his wise patient, and very able administration he has well earned all the respect and esteem in which he is held , and he was thoroughly well served and aided in his work by Surgeon General W H McNamara, M D C.B C.M.G But it is only a special jury as it were, of the medical profession that can appreciate the quality of such services as these it is unfortunately beyond the scope and province of any general officer however eminent, to do so in a way adequate to the occasion. We heartily congratulate all of those whose names have appeared in Lord Kitchener's despatch, extracts from which will be found in another column of THE LANCET

EGYPTIAN MEDICAL CONGRESS

THE following gentlemen have consented to join the committee in England on behalf of the Egyptian Medical

Congress which will be held at Cairo on Dec 19th–23rd next Special facilities and reduction in fares are arranged for members desiring to be present at the Congress Anyone wishing for further information should apply to any member of the committee or to the honorary secretary, 9, Manchester square, London List of the committee Sir Lauder Brunton, Mr Watson Cheyne, Sir William Church, Bart., Mr Reginald Harrison, Sir Victor Horsley, Dr Stephen Mackenzie, Sir Douglas Powell, Bart , Dr George Savage, Sir Thomas Smith, Bart , Dr James Taylor, Sir Frederick Treves, Bart., and Dr W Page May (honorary secretary)

MUNICIPAL MILK DEPOTS FOR HAND-FED INFANTS

A COMPARISON of the death rate of infants under the age of one year with that of the general population reveals the important fact that whereas the latter is steadily decreasing the former is increasing, thus comparing two decennial periods, the annual death rate per 1000 persons living, from 1881 to 1890 was 19 1 and the rate from 1891 to 1900 was 18 2, whereas the mortality rates per 1000 infants under a year old for the same periods were respectively 142 and 154 In these circumstances the great increase in the custom of feeding infants artificially instead of by the natural process of suckling requires careful consideration, especially since a very considerable proportion of deaths of infants are returned as due to gastro enteritis, marasmus, wasting, and other conditions directly or indirectly connected with the alimentary tract and digestive processes It is moreover, certain that very general ignorance prevails as to the process of ' humanising" cow's milk for infant feeding and as to the quantities necessary at different ages, not only among the poor but even among the well to-do and the very extensive and unnecessary use of patent foods for young infants is an evidence of this In France, owing to the extreme importance of this question in relation to the maintenance of the population, early attention was directed to it by hygienists and philanthropists As long ago as 1891 Dr Leon Dufour started an institution for the supply of sterilised humanised milk for infant feeding This was called " La Goutte du Lait.' Havre, Rouen, Paris, and many other French towns adopted the system with beneficial results Similar institutions have in the last three years been started in certain English towns The first was St. Helens, where Dr F Drew Harris introduced the system in the summer of 1899 Liverpool afterwards followed and now has two such milk depôts, and similar ones have been started at Ashton under-Lyne and Dukinfield. In the county of London the first depôt has been started by the Battersea Borough Council during the last two months at the suggestion of Dr G F McCleary, the medical officer of health of the borough The depôt is at 28, York road Battersea, and at present as many as 400 infants can be supplied The price charged to the parents for the full weekly supply is 1*s* 6*d* , or for one day 3*d* The milk is supplied in stoppered bottles, each containing one feed, suited to the age of the infant and the day's bottles (six, seven, or nine in number, according to the age) are fitted into wire baskets conveniently shaped for carrying Rubber teats which can easily be cleaned are supplied to fit on to the bottles and directions are given not to remove the stoppers until the bottle is required for a meal, when it is to be warmed, then opened and the teat put on. The preparation of the milk is as follows The milk (guaranteed free from chemical preservatives) is received directly from a farm in the country which is always open to inspection by the medical officer of health of the borough It is then humanised by the addition of water, cream, and lactose in the requisite proportions (these are given in a leaflet distributed from the depôt) Afterwards it is put into the bottles which have been cleaned and scalded by special apparatus, and subsequently into a steam steriliser and there kept at boiling point for 15 minutes The milk so treated shows no scum, has practically the normal taste, and is much more palatable than is boiled milk. Battersea may be congratulated on this attempt to deal with a very serious problem, and it may well be hoped that this and similar depôts may serve the wider purpose of diffusing a knowledge of the right composition of an infant's diet when for any reason hand-feeding is a necessity

"THE MIASMA OF APPREHENSION"

MR. WYNDHAM, the Chief Secretary for Ireland, in the course of a debate in the House of Commons on July 23rd, used a metaphor which is worthy of note. The sentence in which it occurs is quoted in a leading article in the *Times* as being a good description of the present condition of affairs in Ireland. "The union," said Mr Wyndham, "must become intolerable and any development of self-government must remain impossible unless and until the desolating process of social proscription with its attendant miasma of apprehension which penetrates to and paralyses every nerve centre of national life be repudiated by the good sense of the people and suppressed by the power of the Government." This peroration appears to have brought down the House, as the players have it. "Miasma of apprehension" is a little old fashioned Microbes have taken the place of miasmata. We have heard of the microbe of fatigue. Why not the microbe of apprehension? The notion that a miasm should penetrate to a nerve centre is hardly in accord with modern teaching On the other hand, the paralysis of nerve centres by microbes or their products is one for which Mr Wyndham might obtain the support of men of science The Irish Secretary has been practically guilty of a pathological anachronism, for miasmata belong to the days when atmospheric and telluric influences were supreme and a knowledge of nerve centres is modern. We ought, perhaps, to congratulate ourselves that we have a Minister who has so much as heard that there are nerve centres

QUACKS AND ABORTION

WILLIAM HOLLIS, an old man who was sent to penal servitude for life by Mr Justice Wright at Stafford on July 21st, has manifested throughout his long life an extraordinary ardour for a particularly revolting crime Convicted at Stafford 30 years ago of committing criminal abortion he was sentenced to 10 years' penal servitude Immediately upon being set free he committed a similar crime with the terrible result of death to the unfortunate girl. He was this time convicted of murder and condemned to death, the sentence being commuted to penal servitude for life On release, after serving a term of some 20 years he at once recurred to his detestable method of earning a livelihood, describing himself as a "chemist ' and the possessor of unfailing medicinal preventives of pregnancy At the advanced age of 74 years he has now returned to penal servitude for life. What a comment upon modern civilisation such a career forms! While we are on this subject we must refer, as we have frequently referred before, to the extraordinary impetus which certain newspapers seem willing to give to crime. As journalists it is distasteful to us to find ourselves criticising in an adverse manner the tactics and methods of our contemporaries, but we still regret to observe, more than occasionally, the insertion of advertisements which are a direct invitation not only to sexual immorality but to criminal abortion. Pills and potions are still advertised which "remove all obstructions," and nostrums to restore the menstrual flow are purveyed through the agency of journals with a family circulation As every medical man knows, the commonest cause of obstruction to the menstrual flow is pregnancy while it should be obvious even to laymen that the removal in such a case of obstruction to the flow means the performance of criminal abortion. We consider that the papers which insert advertisements of such ' female remedies are earning dirty money As a matter of fact, the remedies are generally inert, although occasionally death follows their use but they are bought by women in the hope that thei ecbolic action will be effective. Either the woman is helped to a crime when she buys them or she is swindled out of her money Since the publication of our series of articles in 1898 and 1899 entitled, Quacks and Abortion these advertisements have been much fewer but they still appear That the *trade in abortifacient* pretending to be emmenagogues, will altogether cease, or that no newspaper will be found ready to make a disreputable profit by advertising such wares, is, perhaps too much to expect until a prosecution has been undertaken against some journal wherein a more flagrantly outspoken advertisement than usual has appeared. If undertaken with success, such a prosecution would we believe stamp out all these invitations to crime, and with their extirpation the trade in abortifacients would be reduced to a minimum.

ORAL SEPSIS AND ITS RELATIONS TO GENERAL DISEASE

THE July issue of the *Journal of the British Dental Association* contains a paper by Mr J F Colyer dealing with this interesting subject. The writer groups together the various affections in which a relationship between oral sepsis and general disease has been traced and points out that the subject is one in which much more work, clinical bacteriological and chemical must be done before a correct idea can be formed of the exact relationship which does exist. He points out that there are but few really well recorded cases, the exact oral condition being seldom adequately described and he utters a word of warning against too hurriedly assuming that a septic mouth is the direct cau e of some remote affection merely because the remote affection disappears *on removal* of the sepsis. In discussing chronic lymphadenitis he points out that although the statistics of different investigators present wide differences in the results obtained they nevertheless *demonstrate* a close relationship between septic teeth and lymphadenitis and that it is probable that the bacillus tuberculosis may occasionally obtain entrance to the inflamed glands *viâ* the septic teeth A point of *importance to which attention is directed* is that teeth with partially formed root cau e more trouble than those with fully formed roots Some interesting cases are recorded in which gastric ulcers of long standing were cured by the treatment of the septic state of the mouth. In one case a woman, aged 29 years was admitted to the Beckenham Cottage Hospital at Christmas, 1901 under the care of Dr R. M H. Randell. She was in a moribund condition and had vomited large quantities of blood and the pulse when it could be counted, was about 120 She was placed in bed on her back and a quarter of a grain of morphia was administered hypodermically She was fed per rectum with nutrient suppositories and enemata of plasmon dissolved in water A lead and opium pill of five grains was given by the mouth twice daily At the end of three days the hæmorrhage ceased and water was given by the mouth The mouth was in a fetid state with pus oozing from the sockets of the teeth As soon as the patient had sufficiently recovered an anæsthetic was administered and the mouth was cleared of all septic teeth She made a rapid recovery and has had no recurrence of the gastric ulcer In another case a female, aged 26 years wa admitted to the Beckenham Cottage Hospital in December, 1900 with the following history For seven years she had suffered from symptoms indicating gastric ulcer, she had been in many hospitals with invariably the same result—namely, recovery for a time followed by relapse At the time of admission there was copious hæmorrhage. Her mouth was in a most septic state and all her teeth were removed. Immediate improvement resulted and there has not been the slightest return of gastric trouble. The writer of the paper points out that as *recoveries so soon followed the treatment of the mouth it* might be assumed that the gastric disturbance was the direct result of the septic mouth. In considering this question there are, he thinks three points to keep clearly in mind (1) that the *present knowledge of the* pathogenesis *of* gastric ulcer does not support the idea (2) that in many cases of undoubted gastric ulcer the conditions of the mouth are normal and (3) that in the cases which he records there is no direct evidence of cause and effect. In dealing with affections of the blood reference is made to Dr William Hunter's work on Pernicious Anæmia, and the writer remarks that in the cases recorded by that author it is very difficult to form a correct idea of the dental condition Cases of chlorosis Mr Colyer considers, are occasionally traceable to absorption of septic matter from the mouth, and he remarks that it is interesting to note that septic absorption from the mouth may be a possible factor in the production of both pernicious anæmia and chlorosis, the one a disease due to destruction of the blood the other a disease due to diminished formation of blood. Chemical and bacteriological examinations of septic saliva will very possibly show that the septic condition producing or related to, the one differs from that related to the *other* In *remote affections due to absorption* of bacterial products attention is directed to the frequent association of a condition of general malnutrition with a septic condition of the mouth and to the rapid improvement which is made by such patients after the removal of the sources of sepsis and before the adoption of artificial dentures He considers these cases of general debility are in reality cases of chronic sapræmia. The possibility of the mouth being occasionally the focus of infection in obscure conditions such as acute osteomyelitis and malignant endocarditis is discussed and reference is made to two interesting cases recorded in THE LANCET of March 22nd 1902, p. 807 by Dr Belloi. Both were cases of general infection and in both cases the probable focus of infection was the mouth. In the first case the sequence was as follows (1) a history of suppurative periodontitis and gingivitis followed by (2) a catarrh of the larynx and pharynx which subsequently assumed a suppurative type, probably by direct infection from the mouth and (3) general infection from suppuration in the middle ear In the second case the sequence was as follows (1) suppurative periodontitis and gingivitis (2) septic tonsillitis and (3) general infection

A PRIZE IN PHYSIOLOGY

Professor Joseph Seegen has written a letter to the Imperial Academy of Sciences of Vienna in which after a brief reference to the researches that have been undertaken by various observers to determine whether part of the nitrogen of ingested albuminates is eliminated in the form of gas from the system the results of which have been contradictory he states that he in coöperation with Nowak himself, attempted to solve the question but now that he is advancing in years and has had his attention directed to other subjects he does not feel tha he is competent to undertake an inquiry in which he feels the keenest interest. He therefore proposes to offer a prize under the auspices of the mathematical and natural science class of the Imperial Academy for the best answer to the following question Whether any part of the nitrogen of the albuminates which have undergone metabolism in the animal body is eliminated either by the lungs or by the skin in the gaseous form? The value of the prize so liberally offered by Professor Seegen is 6000 kronen, or about £210 The essays must be sent in before Feb 1st, 1904, and may be written in German, French, or English Here is an opportunity of distinguishing himself for one of the numerous workers at our great universities. Will no one take up the gauntlet?

EPSOM COLLEGE

FOUNDER'S Day was celebrated at Epsom College on Saturday last, the chief prizes being presented by Sir Joseph Fayrer, Bart, the chairman of the council, in the unavoidable absence of the Bishop of Winchester, the Visitor of the college, who was to have attended, but who had received a Royal summons There was a large attendance of parents and friends of the pupils, and amongst members of the council on the platform were Dr Holman (the treasurer), Mr Stamford Felce, Mr H W Kiallmark, Mr W A. Propert, and Dr Sansom In his review of the school year the head master, the Rev T N Hart Smith, drew attention to the fact that no fewer than nine old Epsomians had fallen in the South African war, in memory of whom it was proposed to place a tablet in the college chapel Amongst the distinctions gained since Founder's Day, 1901, may be mentioned an open science scholarship at Sidney Sussex College, Cambridge After the distribution of the prizes Sir Joseph Fayrer gave a short address, prefacing his remarks by observing that although during a long life he had found himself in some strange positions that was the first occasion upon which he had been asked to take the place of a bishop He laid emphasis upon the fact that Epsom College was not a "class" school and stated that boys were prepared, not only for the medical profession, but also for the army, the navy, and for commercial pursuits As to the soundness of the education provided, that was proved by the successes won by the boys after leaving the college At the conclusion of the proceedings the "Canticum Epsomiense" and the National Anthem were heartily sung, after which cheers were called by the head prefect for the council, the ladies, and the visitors.

CHOLERA IN EGYPT

ON July 16th news reached the Sanitary Department in Cairo that several suspicious cases of vomiting and diarrhœa, six of which had proved fatal, had occurred in the little village of Mousha, near Assiout, in Upper Egypt. Mr A. T White, M R.C S Eng, at once hastened there from Assiout and took all the necessary precautions in the event of the illness proving to be cholera. However, the fæcal matter which he sent to Cairo for bacteriological examination proved not to contain comma bacilli and it was at first hoped that the malady might prove to be ptomaine poisoning But Mr Graham, the acting head of the department, wisely decided to neglect no chances and sent up immediately Dr C Goodman to investigate the cases and the origin of the outbreak, and Dr Dreyer with a bacteriological outfit accompanied by pumps for providing a pure supply of drinking water Mousha possesses no resident medical man, and as it is supplied with six wells from which the inhabitants drink it looked as if there could hardly be one common cause of contamination But it is near Assiout, whence there is a caravan route from Kosseir on the Red Sea Coast, and there is no reason why cholera bacilli should not have been introduced in this way by pilgrims returning last month from the holy places It must be remembered that in all previous cholera outbreaks in Egypt the poison has been introduced directly or indirectly by returning pilgrims All necessary precautions have been taken in Mousha itself and everywhere else where cases have been discovered, for unfortunately individuals have already carried it with them to the Fayoum and to Cairo In the capital there is the usual scare among those classes of the population who possess neither courage nor self control. The English regiments have been marched out to the desert at the Pyramids and to Helwan, not because they already have cholera, but because it is quite a proper precaution to be taken in the circumstances Major-General Sir R. Talbot, Colonel W J Fawcett, R.A.M C, Principal Medical Officer of the Army of Occupation, and Sir H. H Pinching, Director-General of the Sanitary Department, have decided to return to Cairo from leave and are now on their way there. It is to be hoped that the present anxiety will not last long, for the chief ally of sanitary officers, the Nile flood, is now due both in Assiout and in Cairo, and the experience of former epidemics shows that cholera in an epidemic form does not occur after the annual rise of the Nile In 1883 cholera ended in Cairo in August, though it afterwards broke out in the neighbourhood of Alexandria, and on its last visitation in 1896 it yielded in August to the bountiful supply of fresh water Therefore, if Egypt must be visited by cholera, it is better that the outbreak should begin in July instead of in the spring months as in former epidemics

SIMULATION OF STRICTURE OF THE ŒSOPHAGUS BY ATROPHIC RETRACTION OF THE STOMACH

AT the meeting of the Société Médicale des Hôpitaux of Paris on June 27th M. Maurice Soupault called attention to the fact that in atrophic retraction of the stomach the symptoms may closely simulate those of stricture of the œsophagus The patients having suffered for months or years from gastric symptoms manifest difficulties of deglutition First solids, then semi liquid food, and, finally, liquid foods are swallowed with difficulty Food taken slowly and in small quantities may be retained but when taken rapidly or in moderate quantities it is vomited. Sometimes the vomit contains both the food which has been just swallowed and also the residue of food taken previously The patients do not complain of pain as in stricture of the œsophagus but rather of a feeling of epigastric weight. As a result of the dysphagia they rapidly waste, which confirms the supposition of organic obstruction of the œsophagus But the largest bougies can be passed. If water is introduced into the stomach by a tube it is found that the capacity of the viscus is small and when the limit is exceeded vomiting is produced and the liquid flows back through the œsophagus and mouth outside the tube. This phenomenon is characteristic. The area of gastric resonance is reduced or cannot be found. In two cases M Soupault felt in the upper part of the epigastrium a hard tumefaction—the retracted and thickened stomach The food vomited shows none of the reactions of substances which have been in the stomach some time, for the secretion of gastric juice is suppressed The anatomical condition always found was great reduction in the capacity of the stomach from retraction and thickening of its walls Of four cases examined there were infiltrating cancer in three and cicatricial sclerosis due to corrosive poisoning in one. The following case is an example. A woman, aged 56 years, entered hospital complaining of dysphagia. For four months she had had pains in the stomach which came on immediately after taking food and were sometimes followed by vomiting After the first month she could not take solid food. When she ate she felt a weight at the pit of the stomach , the food was vomited in about half an hour Liquids at first were better tolerated but in the end they were also vomited. She rapidly wasted. When she entered hospital she was greatly emaciated and refused all solid food. Liquids which were taken were vomited in small quantities. As her appetite was well preserved she constantly made attempts to take food and spent the whole day vomiting The vomit was of neutral reaction and milk was returned not curdled. Stricture of the œsophagus was suspected but a bougie could be passed into the stomach. In the epigastrium tympanitic resonance could not be obtained , a diffuse induration was felt which was attributed to muscular resistance. The patient became weaker and weaker and died after 25 days residence in the hospital. The necropsy showed that the stomach was very small and formed a mass at the upper part of the epigastrium its walls were thickened and sclerosed There was infiltrating cancer which extended through the whole viscus from the cardia to the pylorus. The œsophagus was permeable. M. Soupault related three other cases and quoted five more showing that atrophic retraction of the stomach may simulate stricture of the œsophagus The differential diagnosis can always be made by passage of a bougie.

A CRUSADE AGAINST SPITTING

THE Public Health Department of the City of London is embarking upon a crusade in which it will have the sympathy of every decent man and woman and equally it is to be hoped the active support of public bodies and large employers of labour The department has issued a circular asking for coöperation in preventing so far as possible the growing habit of spitting in the streets and other places of public resort." The objectionable nature of this practice on grounds of ordinary cleanliness need not be emphasised It becomes painfully obvious to all who travel by public conveyances and who some day or other have the misfortune to be to windward of the careless expectorator of the omnibus-top. Nor need we lay stress upon the serious import as a means of spreading tuberculous infection that indiscriminate expectoration bears in public places. Our readers are well aware that, whatever may be the result of the commission inquiring into the power of infected food to spread tubercle amongst us, there is no doubt in the mind of any authority upon the subject that the most formidable vehicle of infection of all is the sputum of tuberculous persons. The Public Health Department of the City of London very rightly draws attention to this in its circular and appeals to employers of labour to assist the corporation in attempting to remedy the nuisance by directing the attention of employés to the evils of the habit and to the importance of suppressing it The whole question is really one of educating the public. It is not essential to anybody s comfort or safety that he should expectorate freely into the air or on to the ground about him When all his fellow men and women realise this they will taboo the indiscriminate expectorator At present his performance is regarded largely as a matter of course The working man or woman by his side knows nothing of the possible danger and is not yet nice" enough to deplore the nastiness of the ca ual expectoration of a neighbour Our medical readers can more than any other class of men assist public bodies in the education of the public mind in this matter We are glad to see that the City of London is not alone in taking or even the first to take, the field against expectoration in public places. The interim report of the National Association for the Prevention of Consumption and other Forms of Tuberculosis (July 14th) shows that, in consequence of the activity of the association already both in Glasgow and in Liverpool the corporations have inserted a clause in their by laws making spitting on the municipal tramway cars a finable offence. The metropolis in many similar matters is wont only to follow instead of to lead the steps taken by other cities. It is to be hoped that it will not be long before the example of Liverpool and Glasgow in this matter is widely followed in the public conveyances of London

CONGRESS OF THE SANITARY INSTITUTE

THE nineteenth Congress of the Sanitary Institute will be held in Manchester from Sept. 9th to 13th, when the Right Hon. the Earl Egerton of Tatton will preside. From the preliminary programme which has just been issued we notice that there will be three general addresses—namely the Presidential Address the Lecture to the Congress" to be delivered by Mr W N Shaw, D Sc., and the 'Popular Lecture" to be delivered by Sir W J Collins, F R.C.S. L.C C There will be three sections meeting for two days each Section 1 Sanitary Science and Preventive Medicine, President, Sir James Crichton Browne, F R S. Section 2 Engineering and Architecture, President, Sir Alexander Binnie Section 3 Physics Chemistry and Biology President, Professor Sheridan Delépine. Conferences will be held of municipal representatives, port sanitary authorities, medical officers of health, engineers and surveyors, veterinary inspectors, sanitary inspectors, as well as conferences on Domestic Hygiene and the Hygiene of School Life. In practical illustration of the application and carrying out of the principles and methods discussed at the meetings a health exhibition of sanitary apparatus and appliances will be held and there will also be excursions to places of interest in connexion with sanitation Conversaziones and other social gatherings will also form a feature of the congress. The local arrangements are in the hands of an influential local committee, presided over by the Right Hon. the Lord Mayor of Manchester with Mr J H Reynolds Principal of the Municipal School of Technology as honorary secretary

ADIPOSIS DOLOROSA

RECENT researches have shown that adiposis dolorosa—a condition in which great accumulation of subcutaneous fat takes place and in which the fat is often aggregated into nodules or lumps which are painful to touch and to pressure—is different from simple obesity and that definite changes in the peripheral nerves are present in this malady Professor F X Dercum and Dr J McCarthy have reported in the *Philadelphia Medical Journal* of July 5th a case of this affection running a typical clinical course and terminated by erysipelas. At the necropsy the following interesting changes were discovered The pituitary gland was the seat of an adeno-carcinoma. Interstitial neuritis was present in the subcutaneous fatty tissue especially in the fatty nodules Free hæmolymph glands were present in the tissues of the body generally and the spleen was the seat of an angioma. The subcutaneous fat showed a peculiar cauliflower like arrangement." Professor Dercum and Dr McCarthy stated that in several of the cases of adiposis dolorosa in which necropsies had been made it had been found that the cerebral convolutions were atypical They regarded this as an interesting coincidence probably without significance. In the discus ion which followed the reading of the above paper at the American Neurological Association Dr Putnam remarked that patients suffering from adiposis dolorosa showed various signs of defective or anomalous development—so-called anatomical stigmata" of degeneration—as regarded their bodily organs or tissues Dr F S. Pearce agreed that neuritis was present in the nerves contained in the fatty nodules, whereas in ordinary obesity such changes were absent. Professor Dercum and Dr McCarthy stated that the pathogenesis of the disease was obscure and its treatment unsatisfactory, and that much yet remained to be discovered in these directions.

A METHOD OF PHOTOGRAPHING PLATE-CULTIVATIONS WITHOUT REPRODUCING THE SCRATCHES OF THE DISH

IN photographing plate cultivations which have been made in scratched dishes the scratches are sometimes only too faithfully reproduced, interfering very much with the photographic detail of the cultivation. In valuable cultivations this is a source of considerable annoyance. Mr. Walter A. Mitchell, of the pathological laboratory at Cambridge, avoids the photographic reproduction of the scratches on the cultivation dish by putting a drop of cedar wood oil thinned with xylol on the bottom of the dish after it has been thoroughly cleansed with swabs of wool soaked, first in hydrochloric acid and then in water. The oil is well rubbed in with the finger tips. It is important that the oil should not be too thick and that it should be well rubbed in so that no scratches are visible. The best result is obtained when the oiling is done 20 minutes or so before the photograph is taken. We have received for inspection (1) a photograph of a gelatin culture in a dish which was purposely badly scratched and then thoroughly cleansed in the way indicated, and (2) a photograph of the same dish taken with the same lens, with the same stop exposure and lighting arrangement but with one-half of the dish oiled. The advantage of this simple method is obvious from the latter photograph, the scratches being quite eliminated. Every bacteriologist knows how easily cultivation dishes are scratched, and in research with mixed cultures it is impossible, as Mr. Mitchell points out, to duplicate a plate should it be scratched and a photograph of it be desired.

THE TREATMENT OF RELAPSING PLEURAL EFFUSIONS BY GASEOUS INJECTIONS

AT the meeting of the Société Médicale des Hopitaux of Paris on May 23rd M. Vaquez and M. Quiserne called attention to the value of gaseous injections in the treatment of recurring pleural effusions. Their method is directly derived from that of the late Professor Potain. It consists in producing an artificial pneumothorax which checks the incessant reproduction of fluid observed in certain cases of chronic pleurisy. They suppose that the mode of action is purely mechanical. The choice of the gas used depends on its greater or less absorbability rather than on any antiseptic power. The following case is an example. In January, 1902, a man had been under treatment for left tuberculous pleurisy since May, 1901. Paracentesis had been performed 12 times, 1000 to 1500 grammes of fluid being removed on each occasion and the effusion being reproduced in from three to five weeks. The general condition of the patient was not bad; he had no fever and took food well. He could go about except during the eight or ten days preceding paracentesis when increasing dyspnœa kept him in bed. On Jan. 7th a litre of serous fluid was removed. On the 21st the effusion was reproduced and a litre of fluid was again removed, and with the apparatus devised by Professor Potain about three quarters of a litre of air were injected. The pleura was evidently very thick and hard, for it offered great resistance to the passage of the trocar. An hour later the temperature was elevated to 104° F. and the patient felt ill, but in the evening the temperature returned to normal. Immediately after the injection all the signs of hydro-pneumothorax were present. Pneumothorax persisted until April 28th—more than three months. Only a small quantity of fluid at the base of the lung could be demonstrated. Further intervention does not seem to be necessary. In another case a man had tuberculous pleurisy which began in October, 1901. In March, 1902, paracentesis had been performed five times. On March 27th paracentesis was performed and three quarters of a litre of sterilised air were injected. No reaction followed. Signs of pneumothorax lasted for two weeks. At the end of April the patient left the hospital greatly improved. For the injection of gas into the pleura a trocar connected with a Y shaped indiarubber tube is required. One branch of the tube is connected with a Potain's syphon, the other remains free and is provided with an ampulla of glass filled with sterilised cotton wool. Before use the tubes are carefully boiled. The free branch of the Y is clamped with an artery forceps while the paracentesis thoracis is performed. Then the forceps is transferred to the other arm of the Y and an air pump is connected with the free arm. Air is injected slowly into the pleural cavity and is sterilised in passing through the cotton-wool. If it is desired to inject any other gas that can be easily done from a bag filled with it. The quantity of gas to be injected depends on the amount of fluid withdrawn; in most cases half a litre is sufficient. The capacity of the pump being known the number of strokes of the piston shows the quantity injected. As to the question of the gas to be injected air appears to answer very well in the majority of cases. As shown in the first case it is slowly absorbed. But if the effusion is rapidly reproduced nitrogen, which is very slowly absorbed, may be used. It has been ascertained that after air is injected into a serous cavity only carbonic acid and nitrogen remain. The impermeability of the pleura to nitrogen is shown by a case of relapsing staphylococcic pleurisy under the care of M. Widal. After the injection of air the pneumothorax lasted only 10 days; after the injection of nitrogen, at least 25 days. M. Vaquez and M. Quiserne suggest that the injection of air into the pleural cavity may prevent by its mechanical action certain untoward complications of paracentesis thoracis, such as rapid extension of tuberculosis in the compressed lung after it is released from pressure.[1]

MENTAL DISEASE IN ARMIES

IN a recent issue of the *Allgemeine Zeitschrift für Psychiatrie* (Heft 4, 1902) Dr. Ewald Stier furnishes interesting facts and statistics concerning the graver forms of nervous and mental disease in armies. In military statistics, writes Dr. Stier, a history of lues is almost invariably found to have preceded cases of tabes dorsalis and of general paralysis of the insane in officers. This is especially shown as regards the armies of France, Germany, and Great Britain. The observations of Dr. Stier regarding the almost invariable association of syphilis with general paralysis confirm the conclusions already arrived at by Rieger of Würzburg, and in this country by Dr. W. J. Mickle, concerning the not infrequent occurrence of these associated affections in military officers. In many, but not in all cases, adds Dr. Stier, other causes may also be found—viz., alcoholism and, to a less extent, trauma. Hysteria in males was a rare occurrence in the armies of Europe a quarter of a century ago, but now it is not uncommon, especially, according to Dr. Stier in the armies of central Europe. The traumatic psychoses are found to reach a high proportion only during wars, the chief causes being cranial and other injuries caused by shot or shell, accidents, and shocks sustained in moments of intense cerebral excitement. Thus, in the course of the Franco-German war (1870–1871) the proportion of cases of traumatic psychosis in the German army reached to 13 per cent. of the total number of soldiers engaged in fighting. Medical statistics as regards armies are, in Dr. Stier's opinion, as yet very inadequately drawn up, but this defect will it is hoped be soon removed, as a knowledge of nervous and mental disease and the passing of an examination in the same are now compulsory in the German army

THE BENEFITS OF THE BICYCLE TO MEDICAL MEN

MEDICAL men who have experienced the benefits of the bicycle may be glad to be reminded of the movement which has been started for the establishment of a memorial to the late Mr J K. Starley who introduced the safety" bicycle in 1885 and who died last October The secretary to the fund is Mr R. T Lang of 27 Chancery lane W C. and any medical men who would like to express their appreciation of those benefits in a practical form are invited to communicate with that gentleman Donations have been received from several notable persons including the Prime Minister the Right Hon A. J Balfour M P The fund now amounts to about £200 There is no doubt that the bicycle is especially useful to the country practitioner whose patients reside miles apart It is swift and inexpensive occasions but little trouble, and has many advantages in these respects over the horse and carriage with their inevitable appurtenances The modern medical man is enabled to carry a dispensary and surgery outfit within the compass of a bicycle knapsack. The medical man who needs a bicycle needs one which is thoroughly trustworthy respectable, and reasonably priced The bright parts should if possible be untarnishable, in order to thwart the small boy who never loses an opportunity or a pretext to hail the rider of a machine which fails to come up to his critical standard of refulgency with the epithet of 'old iron

WE have been informed of the army medical arrangements in connexion with the postponed Coronation of their Majesties on Saturday next August 9th and they do not differ greatly from those which we described as having been made for the Coronation at the original date (see THE LANCET June 21st p 1789) The number of ambulance stations had been reduced from 18 to 12, of dressing stations from six to five and of field hospitals from 10 to six, while only four general hospitals—viz. St George's Charing Cross St Thomas's and Westminster—are reserving beds for casualties of a severe nature among the troops The abandonment of the second procession with its extended route accounts for all the changes

Mr M. H Taylor J P L.R.C P L.R.C S. Edin. deputy coroner for the Kingston district of Surrey has been appointed coroner in place of the late Mr A. Braxton Hicks and Mr R Henslowe Wellington L R.C P Lond M R C S Eng has been appointed deputy coroner for the City and Liberty of Westminster and for the south western district of London under the London County Council.

DR. A E. SANSOM having resigned the post of physician to the London Hospital has been appointed consulting physician and has been unanimously elected by his colleagues a member of the London Hospital Medical Council

THE KING has been pleased to appoint Sir Frederick Treves Bart. K.C V O C.B F R.C.S. Eng one of His Majesty's Honorary Serjeant Surgeons to be a Serjeant Surgeon in-Ordinary to His Majesty

WE are asked to state that medical men are required for plague duty in India. Application for appointments should be made to the Secretary Revenue and Statistics Department, India Office

THE ANNUAL REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS FOR THE YEAR 1901

PART I REPORTS

THIRD AND CONCLUDING NOTICE.[1]

LEAD is not only the mineral poison which causes the greatest mortality amongst those engaged in factories and workshops but there can be little doubt that of all metals it causes the greatest number of deaths amongst mankind in general Plumbers and lead painters who do not work in factories do not come under the care of the Home Office, and there are no trustworthy data to go upon to render it possible to make even an approximate estimate of the number of those who are slowly killed by the insidious action of lead. It is nevertheless, certain that the records of the metropolitan hospitals show clearly enough that a very large proportion of the cases of gout and of granular kidney occur in painters and plumbers The house-painter pleases himself as to whether he shall wash his hands before taking his meals and it is the business of no one to provide him with soap or with a nail brush. In the case of the industries which necessitate working in lead in a factory or workshop the employés are under supervision. Of these industries a few words may be said. The smelting of lead has been found to be a particularly injurious occupation At some small works near Dublin of 12 men seven showed a blue line on the gum five were anæmic five had suffered some more than once from colic, three had weakness of the wrists and in two of these cases loss of power ' amounted to definite paralysis " Printers are usually mentioned as men particularly liable to suffer from plumbism, but it does not appear that the number of cases occurring amongst them is very great In the year 1899 the number of reported cases amounted to 26. in 1900 there were 18, and in 1901 there were 23 cases. In the case of compositors more than one of the assigned causes of poisoning are removeable. It is said that some compositors put type in their mouths This is not a commendable habit. It is stated also that when the type is getting low—that is to say when there is little left in the type box—there exists a practice amongst compositors of shaking up the type and that this causes a fine dust of metal to be raised and inhaled It is also stated that in some printing works no washing conveniences are provided and that to quote the words of a report ' cleansing of the hands before meals is not done. File cutters suffer from inhalation of lead dust. Tinners and enamellers have suffered much in the past but it may be hoped that in the future fewer cases of plumbism will occur amongst them. In a case quoted in the report a manufacturer was using an enamel powder which contained no less than 67 per cent of lead oxide. The work people were evidently injured in health by its use. The manufacturer refused to alter his process. The inspector applied for a closing order—that is to say an order from the magistrate that the whole business should be discontinued An adjournment was applied for and granted and in the course of a few days an enamel free from lead and from arsenic was substituted for the injurious compound which had been previously used

Workers in white lead have always been prominent amongst the sufferers from plumbism but it is pleasing to note that the number of the cases is diminishing to a marked extent The number of reported cases for the years 1898 1899 1900 and 1901 was respectively 332 399 358, and 189 This rapid diminution in the number of cases cannot be expected to progress at the same rate for the lessened incidence of the reported cases for the last of these years is chiefly due to improvements in the arrangements of two large factories in which during the previous year there had been an enormous number of cases. During the year 1900 these two firms had amongst their workpeople 111 and 62 cases respectively and during the year 1901 the numbers were reduced to 56 and 16 respectively

A considerable decrease has taken place in the number of cases of lead poisoning which have occurred in workers in the china and earthenware trades. The number of reported cases for each of the four years from 1898 to 1901 inclusive has been 457, 249, 200, and 106 respectively The medical inspector in his special report insists that no diminution in the cases of plumbism occurring in dippers, ware cleaners, and glost placers can be expected unless and until glaze of low solubility is used in the factories, nor can any improvement be hoped for in the case of ware cleaners until efficient fans are introduced to remove the metallic particles which are necessarily given off in the course of the cleansing process

---

[1] The first and second notices were published in THE LANCET of July 19th (p. 172) and 26th (p 238) 1902.

Glass-cutting is an industry in which the workers are subject to plumbism The trade is not a large one and very considerable improvements in the conditions under which the work is carried on have of late taken place. There has been a great increase in the number of cases of poisoning amongst the makers of electrical accumulators—secondary batteries which serve for the storage of electricity This is, of course, practically a new industry In the year 1895 the number of workers was a little over 400, in 1896 it amounted to nearly 550, in 1897 it was 751, and in 1899 it was 1089 Unfortunately no statistics of later date are available. Dr T M Legge, the medical inspector of factories, gives a very full and clear account of the process of manufacture of electric accumulators, of the special regulations in force in Germany in factories where these instruments are made, and recommendations as to rules which he suggests should be put in force in this country There can be no doubt that the stringent regulation of this trade demands immediate attention The number of reported cases of plumbism which have occurred amongst the operatives has greatly increased and in this particular case the experience acquired in Germany may very advantageously be utilised in this country

It may seem at first sight rather curious that workers at factories of paints and colours do not suffer more than they do from lead poisoning and it is rather surprising to learn that there are only 25 such factories in the country During the year 1901 49 cases were reported and of these no less than 35 occurred in men engaged in mixing and grinding the pigments Coach making, it appears, still causes many cases of plumbism, 65 cases were reported during the year and 28 cases occurred in ship builders The medical inspector gives a table of the fatal cases A somewhat similar table was published in the report for the year 1901 and it was then pointed out in THE LANCET that the table was "not sufficiently complete to make it of any clinical value"[2] It was hoped that so gently expressed a criticism might have been sufficient. The table given in the report for 1902, however, shows no improvement. It is incomplete and it cannot truthfully be called useful. The information which the table professedly gives in the case of each patient is as follows sex, age, symptoms, duration of employment, and remarks There were 33 fatal cases Of these the duration of employment is in eight cases very roughly given as "many years," and in 10 other cases it is not given at all Thus, in more than half the cases no definite information is given as to the length of time during which the patient worked in lead There are some curious entries under the heading "Symptoms" For example, in one case the only information is "lead convulsions" in another "lead-poisoning," and in a third "plumbism, phthisis." Phthisis is a disease, not a symptom. Here again is an example of remarkable "symptoms" "violent syncope induced by appendicitis and accelerated by acute lead-poisoning"

The Chief Inspector's general report deals in some detail with the arbitration which was lately held in regard to the special rules drawn up by the Home Office to regulate the earthenware and china factories Reports of this case have already been given and it is not necessary here to recapitulate the history of the proceedings, an account of which may be found on pages vii and viii. of the report. The only point to which we need direct attention is the anomalous state of things which has been brought about in the regulation of this industry as a result of the administration of the Factory Acts. The facts briefly are these. 1. Under the award of Lord James of Hereford, the umpire in the arbitration case, the amended rules in regard to the trades are now in force in the works of 345 occupiers who appointed an arbitrator 2. Another award in respect to 36 out of a total number of 46 manufacturers who objected to the rules but did not name an arbitrator was made in March, the award then made was in effect the same as that of Lord James In regard to the 10 other cases no decision has been arrived at. 3 153 manufacturers either did not object to the amended rules or withdrew their objections In the case of these 153 firms the draft rules of February, 1901, are therefore legally in force 4 There are 95 businesses in which rough ware is made under conditions different from those in use in the manufacture of ordinary pottery On these firms the notices were not served and therefore, as Dr B A. Whitelegge, who apparently for once uses what may be called the "official gloss" has it, "these firms remain for further consideration." The report, however, shows in a most convincing manner that the officers of the Home Office are doing their utmost to place these dangerous trades under proper regulations and the fact that there has been some delay in doing so is no fault of theirs It must also be pointed out that reforms of too radical a character often defeat their own ends and that the chief hope for lasting improvement is to be found in progressive improvements in the processes of manufacture Such improvements are fittingly recognised by the Home Office and exemption from some of the general rules in force are granted in certain cases on condition that only materials free from lead are used in the factories

A brief reference has already been made to Mr C R Pendock's report on the fencing of machinery at the Paris Exhibition, 1900, but there are one or two points in regard to it which seem to demand further consideration In his introductory remarks Mr Pendock points out that the date of his visit was not altogether favourable to his mission, the most interesting exhibits were besieged by crowds, the regulations of the Exhibition prohibited the taking of notes and the making of sketches, and, further, the time chosen for the visit was so late that many of the principals of the firms of manufacturers had gone home. It is well known that the greatest courtesy and attention were bestowed by the French Government on foreign visitors, and it is certainly a matter for regret that the Board of Trade should not have sent its representative at an earlier period or made some special effort to ensure that he should have all possible facilities for seeing all that he wished to see Another point is of more practical value, inasmuch as it has reference to the future Mr Pendock's report clearly shows that in the case of newly invented machinery English manufacturers as a rule neglect to provide proper fencing until its necessity is insisted upon by the factory inspectors. This fact is so thoroughly proved that we are decidedly of opinion that the Board of Trade should without delay issue a circular to the chief manufacturers of machinery calling their attention to the matter This is the first step which should be taken and it would undoubtedly be effective in many cases and would lead to the prevention of some of the more obviously unnecessary injuries and losses of life.

Attention has already been called to a most iniquitous illegality which is practised by cotton manufacturers. It is the custom of many of them to make their people work for a longer period than that allowed by the law The time of the men is stolen and not paid for The practice is called "time cribbing" Mr Richmond the chief inspector for the north western division of England, shows that the custom is deliberate and systematic and that "scouts" are placed to give warning by signals of the approach of any stranger who is suspected to be a factory inspector Many prosecutions took place during the year 1901—438 in the north western division—but although there was a conviction in each case the fines inflicted amounted to no more than £180 12*s*, an average of about 8*s* 3*d* each These fines are absurdly small and cotton capitalists must laugh at them One of the Manchester inspectors, Mr Sidney Smith, says that many firms think nothing of running their machinery illegally three, four, five, or more minutes at each starting and stopping time, and then he goes on to show the actual gain to the manufacturers by this piece of dishonesty "Five minutes cribbed at each starting and stopping time amount to a total of 14 days of 10 hours per annum and this amount is practically stolen from those workers who are paid weekly wages" Mr Crabtree of Oldham says that the majority of cotton mills crib time in that way and he adds "the scandalous part of it is that directors, managers, and overlookers all know of it." It appears to us that the chief inspector might very usefully publish each year a list of those firms which are convicted If the statements made by the inspectors are accurate—and we have not the slightest reason to doubt their absolute accuracy—the directors of these cotton firms would be more fitly punished by imprisonment than by fine.

---

[2] THE LANCET Oct 12th 1901 p 1000

Felt-hat factories have been placed under special regulation as a result of an explosion in the Denton hat factory which killed 14 and injured 50 other people—a fact which convinced the manufacturers that their trade might not improperly be called dangerous

The local sanitary authorities in many places still flagrantly neglect to carry out the duties with which they are entrusted For example at Nantwich where a large clothing trade exists, not only are the sanitary conveniences inadequate and unsatisfactory but it has been conclusively proved also that it has been quite a common thing for clothing to be made up in houses in which some of the inmates have been suffering from scarlet fever Mr. Sidney Smith of Manchester also reports that the sanitary conveniences in some of the cotton mills are a disgrace to the community' They appear in fact, to resemble those in use in English castles in the Norman period A common system, he says appears to be an ordinary brick tower extending from the top of the mill to the bottom, the conveniences are entered from the door opening directly into the workrooms and are so situated that the excreta can fall down the tower into a large open midden placed at the bottom Many examples of this style of jakes—(Mr Smith calls them closets but this is evidently a misnomer)—have recently been found at Stalybridge Hythe, Dukinfield and Macclesfield

A very remarkable example of money lending in the North of Ireland has been brought to light by Mr Snape The cashier of a flax spinning company was accustomed to lend to workmen the sum of 10*s* on a certain date and on the next following pay-day (about 14 days after) he deducted from the workman's wages 12*s*. 6*d* the additional 2*s* 6*d* being for interest. The rate of interest charged therefore, was about 650 per cent per annum an amount which would usually be considered somewhat excessive. This case appears worthy of the investigation of the senior Member for Northampton. The duty of seeing that the Truck Act is rendered operative must be no light one and the duty of aiding voluble and incoherent female operatives" might perhaps with advantage be left as much as possible to the women inspectors

The report on the work of the women inspectors is provided with a table of contents" which serves as a sufficient index. The most interesting part is perhaps, the account given of egg factories as they are called places in which foreign eggs are selected pickled and kept, and finally packed for distribution Broken eggs we find, are deprived of their shells and put into tins and sold to confectioners under the name of *mélange*. Broken eggs of more than doubtful character are mixed with salt and sold to leather dressers. The lady who reports on this absorbing subject states that in the winter season bad eggs are seldom met with" and this is perhaps not what may be called a matter of common knowledge nor is it a matter of universal experience. Many of the reports of the women inspectors are much marred by the terms in which they are written and the plethora of adjectives

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 6658 births and 3976 deaths were registered during the week ending July 26th. The annual rate of mortality in these towns which had been 14 3 and 14 5 per 1000 in the two preceding weeks, declined again last week to 13 9 per 1000 In London the death rate was equal to 14 3 per 1000 while it averaged 13 8 in the 75 other large towns. The lowest death rates in these towns were 3 2 in Hastings 4 1 in Hornsey 4 8 in Grimsby 7 3 in Smethwick, 7 8 in Tottenham and in Preston 8 1 in Leyton and 8 3 in Newport (Mon.) the highest rates were 18 4 in Hanley 19 2 in Great Yarmouth 19 5 in Birkenhead 20 0 in Merthyr Tydfil, 20 2 in South Shields 21 5 in Liverpool and 24 4 in Bootle. The 3976 death in these towns last week included 552 which were referred to the principal infectious diseases against 533 and 558 in the two preceding weeks, of these 552 deaths 138 resulted from diarrhœa, 118 from measles 112 from whooping-cough 83 from diphtheria, 53 from scarlet fever 42 from fever (principally enteric) and seven from small pox. No death from any of these diseases was registered last week in Croydon Hastings Brighton Great Yarmouth Smethwick, Grimsby Stockport St. Helens, Halifax York or Stockton-on Tees while they caused the highest death rates in Portsmouth, Hanley Burton on Trent Bootle Burnley Gateshead, Rhondda and Merthyr Tydfil The greatest proportional mortality from measles was recorded in Portsmouth, Plymouth, Devonport, Bristol, Burton on Trent, Derby, Rochdale Gateshead and Rhondda from scarlet fever in Burnley from diphtheria in Bury Middlesbrough Rhondda and Merthyr Tydfil from whooping-cough in Portsmouth Norwich Hanley and Barrow in Furness, and from diarrhœa in Norwich, Liverpool Bootle, Gateshead and Merthyr Tydfil. Of the fatal cases of small pox registered last week four belonged to London and one each to Tottenham, Birmingham and Swansea, but not one to any other of the large towns. The Metropolitan Asylums hospitals contained 369 small pox patients on Saturday July 26th against numbers decreasing from 1515 to 459 on the 13 preceding Saturdays 23 new cases were admitted during the week, against 58 51 and 48 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital which had been 2432, 2352, and 2377 at the end of the three preceding weeks had further risen to 2486 at the end of last week 397 new cases were admitted during the week, against 255 272, and 333 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London which had declined from 194 to 155 in the four preceding weeks further decreased last week to 128 and were 43 below the corrected average number The causes of 38, or 1 0 per cent. of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Nottingham, Salford, Bradford Leeds, Sheffield Newcastle, and in 51 other smaller towns, the largest proportions of uncertified deaths were registered in Birmingham, Liverpool Rotherham Hull South Shields and Gateshead

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns which had been 16 3 16 2 and 14 7 per 1000 in the three preceding weeks rose again to 15 8 per 1000 during the week ending July 26th and exceeded by 1 9 per 1000 the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 8 3 in Paisley and 10 9 in Aberdeen to 17 3 in Dundee and 18 1 in Glasgow The 512 deaths in these towns included 21 from diarrhœa, 13 from whooping-cough 10 from measles, six from scarlet fever, four from diphtheria, and one from fever" but not one from small pox In all 55 deaths resulted from these principal infectious diseases last week, against 62 and 44 in the two preceding weeks. These 55 deaths were equal to an annual rate of 1 8 per 1000 which was slightly below the mean rate last week from the same diseases in the 76 large English towns The fatal cases of diarrhœa, which had been 15 and 13 in the two preceding weeks, rose again last week to 21 of which 13 occurred in Glasgow and six in Dundee The deaths from whooping cough, which had been 14 and 15 in the two preceding weeks, declined again to 13 last week, and included seven in Glasgow and three in Edinburgh The fatal cases of measles, which had been 22 and 15 in the two preceding weeks further decreased last week to 10 of which seven were registered in Edinburgh and two in Dundee. The deaths from scarlet fever which had been five two and one in the three preceding weeks, rose again to six last week and included five in Glasgow, where two of the four fatal case of diphtheria were also registered The deaths referred to diseases of the respiratory organ in these towns which had been 87 74 and 62 in the three preceding weeks, rose again last week to 80 and were 24 in excess of the number in the corresponding period of last year The causes of 17 or more than 3 per cent. of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin which had been 18 9 16 9 and 20 9 per 1000 in the three preceding weeks was again 20 9 per 1000 during the week ending July 26th During the past four weeks the death rate has averaged 19 0 per 1000 the rates during the same period being 14 5 in London and 16 4 in Edinburgh The 147 deaths of persons belonging to Dublin corresponded with the number in the preceding week and included 15 which were referred to the principal infectious diseases, against 11, 17, and 14 in the three preceding weeks, of these, eight resulted from measles, three from diarrhœa, one from scarlet fever, one from diphtheria, one from whooping cough, and one from "fever" These 15 deaths were equal to an annual rate of 2 1 per 1000, the death-rates last week from the same diseases being 2 2 in London and 3 9 in Edinburgh The fatal cases of measles, which had been six, six, and eight in the three preceding weeks, were again eight last week The deaths from diarrhœa, which had been two, four, and one in the three preceding weeks, rose again last week to three. The 147 deaths in Dublin last week included 28 of children under one year of age and 42 of persons aged upwards of 60 years, the deaths both of infants and of elderly persons considerably exceeded the numbers recorded in the preceding week. Three inquest cases and two deaths from violence were registered, and 57, or more than a third, of the deaths occurred in public institutions The causes of nine, or more than 6 per cent of the deaths registered in Dublin last week were not certified.

THE SERVICES

ROYAL NAVY MEDICAL SERVICE.

THE following notice is to be substituted for that dated July 16th, 1902, which appeared in the *London Gazette* of July 18th, 1902 —

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Surgeon Arthur Alexander Joseph McNabb has been allowed to withdraw from His Majesty's Naval Service with a gratuity

The following appointments are notified —Fleet Surgeon G S Smith to Deptford Victualling Yard. Staff Surgeon F Fedarb to the *President*, additional, for Survey of Stores at Deptford.

ROYAL ARMY MEDICAL CORPS.

Major W Horrocks, R.A M C, is to retain his appointment as Assistant Professor of Military Hygiene at the Army Medical School, Netley, for a further period of six months from September 1st Major R H Firth, Professor of Military Hygiene at Netley, and Professor A. E Wright, Professor of Pathology, are to go to London with their assistants about August 11th for duty at the Army Medical School, London

IMPERIAL YEOMANRY

The undermentioned officer resigns his commission and receives a new commission subject to the provisions of the Militia and Yeomanry Act, 1901, retaining his present rank and seniority, viz —

Surgeon Lieutenant G W Trouton, West Kent (Queen's Own)

ROYAL ARMY MEDICAL CORPS (MILITIA)

Supernumerary Captain J Clerke to be Captain on the Establishment.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers) 1st Argyll and Bute The undermentioned Surgeon Lieutenants resign their commissions —J W W Penney and H. Sinclair 1st Ayrshire and Galloway Surgeon Captain D Lawrie resign his commission

Rifle 2nd Volunteer Battalion Royal Fusiliers (City of London Regiment), Surgeon Lieutenant M G Foster to be Surgeon Captain 2nd Volunteer Battalion the Royal Scots Fusiliers Surgeon Captain W J Lawrie to be Surgeon-Major 2nd (Earl of Chester's) Volunteer Battalion the Cheshire Regiment Andrew MacLennan to be Surgeon Lieutenant. 3rd Volunteer Battalion the Cheshire Regiment Surgeon Captain T Fennell to be Surgeon Major 2nd (Angus) Volunteer Battalion the Black Watch (Royal Highlanders) Surgeon Lieutenant T W Parkinson resigns his commission 5th (Perthshire Highland) Volunteer Battalion the Black Watch (Royal Highlanders) D M Macdonald to be Surgeon Lieutenant 2nd Volunteer Battalion the York and Lancaster Regiment Surgeon Lieutenant J P Shine resigns his commission. 1st Dumbartonshire Archibald Gilchrist Hay to be Surgeon Lieutenant. 5th (Glasgow Highland) Volunteer Battalion the Highland Light Infantry Brigade Surgeon Lieutenant-Colonel D Cowie is seconded whilst holding the appointment of Senior Medical Officer to the Highland Light Infantry Volunteer Brigade, Surgeon Lieutenant J McKie to be Surgeon Captain.

MENTIONED IN DESPATCHES

In despatches from Lord Kitchener to the Secretary of State for War, dated Cape Town, June 23rd, and published in the *London Gazette* of July 29th, the following names, among others, are mentioned —

Surgeon General Sir W D Wilson, K C M G, who "has given me satisfaction as regards his supervision of his own department, as well as the advice he has given me on sanitary matters"

Imperial Yeomanry, 3rd Battalion —Surgeon Captain R Cattley

Coldstream Guards — Surgeon Major W R Crooke Lawless

Royal Army Medical Corps —Surgeon-General W H. McNamara, C B, C M G, Lieutenant-Colonel H H. Johnston, Lieutenant Colonel H J R Moberley, Lieutenant-Colonel F W Trevor, Lieutenant-Colonel S H Carter, Lieutenant Colonel G E Twiss, Lieutenant-Colonel C Todd, Lieutenant-Colonel G T Goggin, Lieutenant-Colonel R. Jennings, Lieutenant-Colonel J M Irwin, Lieutenant-Colonel G W Brazier Creagh, C M G, Major S Hickson, Major C Birt, Major M P C Holt, Major M W Russell, Major C H. Burtchaell, Major F W C Jones, Major J R. Mallins, Surgeon Major J F Bateson (Coldstream Guards), Major T G Lavie, Captain W W O Beveridge, Captain A. F Tyrell, Captain J C Jameson, Captain G St C Thom, Captain W E Hardy, Lieutenant T C MacKenzie, Lieutenant W A Woodside, Lieutenant L W Harrison, Quartermaster and Hon Captain J H W Beach, Quartermaster and Hon Lieutenant J Tandy, Quartermaster and Hon Lieutenant A. Bruce, Quartermaster and Hon Lieutenant G H. Painton, Quartermaster and Hon Lieutenant A. J Pilgrim

Warrant Officers, Non Commissioned Officers, and Men.—Serjeant Major J J Saunders, Serjeant-Major E W Newland, 1st Class Staff Serjeant J Ritchie 2nd Class Staff Serjeant G Fells, 2nd Class Staff Serjeant H Lattemore, 2nd Class Staff Serjeant J Wilton, Serjeant E Haymes, Serjeant T D Cameron, Lance Serjeant G Darling, Lance Serjeant T H V Coad Lance-Serjeant E A. Hawkey, Corporal S Cowan, Corporal J W Elliott, Lance Corporal W Boutwood, Private H Ebbs, Private J Keefe, Private J Meason, Private A. Holloman, Private F Thomas, Private H D White. Private G W Barfoot, Private A Bass, and Private W W Polla[illegible]

Royal Army Medical Corps (Militia) —Captain A. H. Benson and Corporal R. E Kelly

St John Ambulance Brigade —1st Class Superintending Officer C W Baker and Orderly C Pyewell

Civil Surgeons —Civil Surgeon W F Tyndale, Civil Surgeon E Langley Hunt, Civil Surgeon J Prentice, Civil Surgeon R. Wilbond, Civil Surgeon F Stableford, Civil Surgeon C B Howse Civil Surgeon A. W May, Civil Surgeon P W James Civil Surgeon H. J Crossley, and Surgeon Captain T Moir, Imperial Yeomanry

Army Nursing Service —Superintending Sister Mrs J A. Gray, Superintending Sister Miss M Russell, Sister Miss M. C S Knox, Sister Miss C H. Keer, Sister Miss H L. Neale, Sister Miss E J Martin, Sister Miss G E Saunder, Sister Miss A. A Murphy, Sister Miss A. C L Anderson, Sister Miss A. R. Rose Innes, and Sister Miss A. E Tait.

Army Nursing Service Reserve —Sister H. C Luckie, Sister L. Mitchell, Sister G Black, Sister A F Bedwell, Sister J Creighton, Sister C M. Jones, Sister G Roberts, Sister E M. Monck Mason, and Sister J Halliday

Nursing Sisters (*various colonies*) —Superintendent M Rawson (Victorian), Sister Isobel Ivey (Victorian), Sister M S Bidsmead (Australian), Sister D Peiper (New Zealand), and Sister A. V Pocock (New South Wales)

In one of the earlier paragraphs of the despatches Lord Kitchener says ' I well understand that the accompanying list, which is in continuation of the other lists submitted periodically by me, of departmental, staff, and regimental officers who have in my opinion rendered exceptionally good service during the campaign is incomplete, and that notwithstanding all my care there must necessarily be a proportion of officers omitted who have rendered equal, or even better, service than those who have been mentioned. This, however, is the fortune of war and will, I am sure, be well understood by the army I have been so proud to command."

THE LATE WAR.

We notice elsewhere the last of Lord Kitchener's despatches on the war in South Africa to which probably many medical officers among other people, will turn to see if their names are mentioned in it. We do not think that officers of the Royal Army Medical Corps will be disposed to think considering the duration and all the difficulties of the late war that praise and rewards have been bestowed too lavishly upon their branch of the service

Now that the war is a thing of the past the Boer generals and others are free to speak and they have touched upon some interesting points in the course of their speeches. General Meyer for instance has stated that the Boers never had more than 50 000 men under arms in the field at one time. It is very noteworthy considering the amount of enteric fever that prevailed among the British troops, that the Boers practically speaking escaped that disease According to what General Meyer is reported to have said, they had relatively little sickness of any sort and as far as his knowledge and experience extended, no enteric fever whilst on the veldt. They seem for the most part to have been without ambulances and to have had recourse when sick to some simple vegetable drugs called veldt medicines It is not at all uncommon, of course, for the native population of a country to have a relative immunity from the sickness—typhoid fever for example—affecting new-comers or an invading army Still, General Meyer's statements are interesting and instructive in their way Dr Johann Reinecke, who acted as surgeon to the Boers during the war made his surgical experiences in South Africa the text of his dissertation on the occasion of the degree of M.D being recently conferred upon him by the University of Berlin His dissertation although practical and interesting did not teach anything particularly new to military surgeons. It inculcated the advantages of the *noli me tangere* principle and the application of antisepsis to gun hot wounds and gave illustrations of the stoical fortitude of the Boers which made them the best of surgical patients.

ROYAL ARMY MEDICAL CORPS EXAMINATION

The following is a list of successful candidates at the recent examination in London —

Names	Marks	Names.	Marks.
A. B Smallman	626	C A J A. Balck	540
P Davidson	623	G W Smith	540
W F Tyndale	621	J M H. Conway	538
W P Ellis	609	S. M. W Meadows	535
J McKenzie	603	J W S Seccombe	534
A H. Hayes	590	H. V Bagshawe	529
H J Crossley	587	C V B Stanley	520
N D Walker	584	D S Skelton	519
W B B Taylor	573	H G S Webb	516
R. Storrs	569	W W Browne	510
G T Collins	568	F L. Henderson	510
F A. H. Clarke	554	N E J Harding	500
G A K H. Reed	548	W D C Kelly	500
R L. V Foster	547	R Rutherford	499
B B. Ainsworth	542	W C Rivers	493

CIVIL SURGEONS AND THE WAR GRATUITY

We have been asked by several correspondents whether the war gratuity will be given to Civil Surgeons who have served with the troops in South Africa. Civil Surgeons do not come within the category of those for whom the war gratuity is provided in Army Order 5 1901 and they are therefore not entitled to the gratuity It should be remembered however that all Civil Surgeons employed under contract are entitled to a gratuity of two months pay for a year's service, with an additional gratuity for each completed period of three months service beyond the year

MEMORIAL TO OFFICERS AND MEN WHO FELL IN THE LATE WAR.

On July 27th a mural tablet in coloured alabaster bearing the names of officers and men belonging to Guildford and neighbourhood who have fallen in the late war was unveiled in Holy Trinity Church, Guildford, by Mr Brodrick Secretary of State for War The list includes the names of Captain M L. Hughes, R.A.M.C killed at Colenso mentioned in despatches and Surgeon Lieutenant-Colonel W Wellington Lake, in charge of Hospital at Bloemfontein where he died.

THE MAHSUD WAZIRI DESPATCHES.

The following members of the Indian Medical Service are mentioned for services in the Mahsud Waziri campaign Major Ker, Captain Cox, Lieutenant Pelle and Lieutenant Fry

Her Majesty the Queen will distribute the medals to the members of the staffs of the Imperial Yeomanry Hospitals who served during the late war in the gardens of Devonshire House, Piccadilly on Monday August 11th, at 4 P.M.

The prizes won by the surgeons on probation who were successful at both the London and Netley examinations were presented on July 29th by Lord Roberts at the Royal Victoria Hospital Netley

Correspondence.

"Audi alteram partem."

DIPHTHERIA AND ITS TREATMENT AT COLCHESTER.

To the Editors of THE LANCET

SIRS,—In your issue of July 26th, p. 246 some statements are made by Mr H. Whitby reflecting on myself and in a letter in your issue of July 19th, p 182, there is a letter from Dr G Brown on the same subject—diphtheria at Colchester—which calls for some remarks. Mr Whitby states that three of a family were attacked with sore throat and exhibiting all the signs of diphtheria, that the medical officer of health took swabs from two of the family and declared the results to be negative. I have looked through my list for this year and the only case which tallies with the description in any way is that of a family where four swabs were taken where diphtheria germs were found in three out of the four These cases were notified accordingly and admitted to the infectious diseases hospital. The only other case where more than one swab from a family were examined for him occurred in April, when I had two swabs marked Mrs. J and Mrs or Miss J I could not make out which. No diphtheria germs were found in either of those, but they were swabs taken by Mr Whitby and sent with no comment whatever and so can hardly be the swabs referred to. Since March 22nd I have examined swabs for Mr Whitby from six not four houses, in not one of these have diphtheria germs been found. What the symptoms were I know not, as help of that sort is never given by him but in one case at least the patient, when visited by the sanitary inspector on the day of notification was up and about and opened the door for him. Mr Whitby seems to object to the discovery that none of these cases were cases of diphtheria, using the word in the restricted sense in which it is now usually employed. *A priori*, one would have thought he would have been only too glad to find that this was the case. No subsequent case of diphtheria arose in connexion with any of these cases and I take it none of them developed later any of the characteristic sequelæ which otherwise would surely have been noted. With regard to the comments on antitoxin it would be interesting to know who it is who praises the remedy as infallible, since anybody who knows anything at all about the matter must be well aware that it is far from such having of course, no curative power whatever after a certain period. It would also be interesting to have full clinical details of the two cases—of albuminuria, and of albuminuria and bronchitis, with the reasons if any for connecting the symptoms with antitoxin. I may state that the majority of the cases arising here have been treated at the infectious hospital, and that since I have had charge of the patients there not a single person has ever left with even a trace of albumin present. Mr Whitby finally thinks that it is grave that he should not be permitted to have an opinion other than that manufactured for" him, but surely it is a much graver matter for his patients not to have the benefit of the treatment which has been shown to result in the least percentage mortality to them

Coming now to Dr Brown's letter he states that in July 1901 and subsequently diphtheria in Colchester assumed a less virulent form. I am not for a moment prepared to accept this statement. True, I did not see many of the cases before the middle of July but in the same way Dr Brown did not see many of the cases after that date. He certainly never examined *any* of them. For a time he used to in London and 16 4 in Edinburgh The 147 deaths of persons belonging to Dublin corresponded with the number in the preceding week and included 15 which were referred to the principal infectious diseases, against 11, 17, and 14 in the three preceding weeks, of these, eight resulted from measles, three from diarrhœa, one from scarlet fever, one from diphtheria, one from whooping cough, and one from "fever" These 15 deaths were equal to an annual rate of 2 1 per 1000, the death-rates last week from the same diseases being 2 2 in London and 3 9 in Edinburgh The fatal cases of measles, which had been six, six, and eight in the three preceding weeks, were again eight last week The deaths from diarrhœa, which had been two, four, and one in the three preceding weeks, rose again last week to three The 147 deaths in Dublin last week included 28 of children under one year of age and 42 of persons aged upwards of 60 years, the deaths both of infants and of elderly persons considerably exceeded the numbers recorded in the preceding week. Three inquest cases and two deaths from violence were registered, and 57, or more than a third, of the deaths occurred in public institutions The causes of nine, or more than 6 per cent, of the deaths registered in Dublin last week were not certified.

THE SERVICES

Royal Navy Medical Service

The following notice is to be substituted for that dated July 16th, 1902, which appeared in the *London Gazette* of July 18th, 1902 —

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Surgeon Arthur Alexander Joseph McNabb has been allowed to withdraw from His Majesty's Naval Service with a gratuity

The following appointments are notified —Fleet Surgeon G S Smith to Deptford Victualling Yard. Staff Surgeon F Fedarb to the *President*, additional, for Survey of Stores at Deptford.

Royal Army Medical Corps.

Major W Horrocks, R.A M C, is to retain his appointment as Assistant Professor of Military Hygiene at the Army Medical School, Netley, for a further period of six months from September 1st Major R H Firth, Professor of Military Hygiene at Netley, and Professor A. E Wright, Professor of Pathology, are to go to London with their assistants about August 11th for duty at the Army Medical School, London

Imperial Yeomanry

The undermentioned officer resigns his commission and receives a new commission subject to the provisions of the Militia and Yeomanry Act, 1901, retaining his present rank and seniority, viz —

Surgeon Lieutenant G W Trouton, West Kent (Queen's Own)

Royal Army Medical Corps (Militia)

Supernumerary Captain J Clerke to be Captain on the Establishment.

Volunteer Corps.

Royal Garrison Artillery (Volunteers) 1st Argyll and Bute The undermentioned Surgeon Lieutenants resign their commissions —J W W Penney and H Sinclair 1st Ayrshire and Galloway Surgeon Captain D Lawrie resign his commission

Rifle 2nd Volunteer Battalion Royal Fusiliers (City of London Regiment), Surgeon Lieutenant M G Foster to be Surgeon Captain 2nd Volunteer Battalion the Royal Scots Fusiliers Surgeon Captain W J Lawrie to be Surgeon-Major 2nd (Earl of Chester's) Volunteer Battalion the Cheshire Regiment Andrew MacLennan to be Surgeon Lieutenant. 3rd Volunteer Battalion the Cheshire Regiment Surgeon Captain T Fennell to be Surgeon Major 2nd (Angus) Volunteer Battalion the Black Watch (Royal Highlanders) Surgeon-Lieutenant T W Parkinson resigns his commission 5th (Perthshire Highland) Volunteer Battalion the Black Watch (Royal Highlanders) D M Macdonald to be Surgeon Lieutenant. 2nd Volunteer Battalion the York and Lancaster Regiment Surgeon Lieutenant J P Shine resigns his commission. 1st Dumbartonshire Archibald Gilchrist Hay to be Surgeon Lieutenant 5th (Glasgow Highland) Volunteer Battalion the Highland Light Infantry Brigade Surgeon Lieutenant-Colonel D Cowie is seconded whilst holding the appointment of Senior Medical Officer to the Highland Light Infantry Volunteer Brigade, Surgeon Lieutenant J McKie to be Surgeon Captain

Mentioned in Despatches.

In despatches from Lord Kitchener to the Secretary of State for War, dated Cape Town, June 23rd, and published in the *London Gazette* of July 29th, the following names, among others, are mentioned —

Surgeon General Sir W D Wilson, K.C M.G, who "has given me satisfaction as regards his supervision of his own department, as well as the advice he has given me on sanitary matters"

Imperial Yeomanry, 3rd Battalion —Surgeon Captain R. Cattley

Coldstream Guards — Surgeon Major W R Crooke-Lawless

Royal Army Medical Corps —Surgeon General W H. McNamara, C B, C M G, Lieutenant-Colonel H H. Johnston, Lieutenant-Colonel H J R. Moberley, Lieutenant-Colonel F W Trevor, Lieutenant-Colonel S H Carter, Lieutenant Colonel G E Twiss, Lieutenant-Colonel C Todd, Lieutenant-Colonel G T Goggin, Lieutenant-Colonel R. Jennings, Lieutenant-Colonel J M Irwin, Lieutenant-Colonel G W Brazier Creagh, C M G, Major S Hickson, Major C Birt, Major M P C Holt, Major M W Russell, Major C H. Burtchaell, Major F W C Jones, Major J R. Mallins, Surgeon Major J F Bateson (Coldstream Guards), Major T G Lavie, Captain W W O Beveridge, Captain A. F Tyrell, Captain J C Jameson, Captain G St C Thom Captain W E Hardy, Lieutenant T C MacKenzie, Lieutenant W A Woodside, Lieutenant L W Harrison, Quartermaster and Hon Captain J H. W Beach, Quartermaster and Hon Lieutenant J Tandy, Quartermaster and Hon Lieutenant A. Bruce, Quartermaster and Hon Lieutenant G H. Painton, Quartermaster and Hon Lieutenant A. J Pilgrim

Warrant Officers, Non Commissioned Officers, and Men —Serjeant-Major J J Saunders, Serjeant-Major E W Newland, 1st Class Staff Serjeant J Ritchie 2nd Class Staff-Serjeant G Fells, 2nd Class Staff Serjeant H Lattemore, 2nd Class Staff Serjeant J Wilton, Serjeant E Haymes, Serjeant T D Cameron, Lance Serjeant G Darling, Lance Serjeant T H. V Coad Lance Serjeant E A. Hawkey, Corporal S Cowan, Corporal J W Elliott, Lance Corporal W Boutwood, Private H Ebbs, Private J Keefe, Private J Meason, Private A. Holloman, Private F Thomas, Private H D White Private G W Barfoot, Private A Bass, and Private W W Pollard

Royal Army Medical Corps (Militia) —Captain A. H. Benson and Corporal R. E Kelly

St John Ambulance Brigade —1st Class Superintending Officer C W Baker and Orderly C Pyewell.

Civil Surgeons —Civil Surgeon W F Tyndale, Civil Surgeon E Langley Hunt, Civil Surgeon J Prentice, Civil Surgeon R. Wilbond, Civil Surgeon F Stableford, Civil Surgeon C B Howse Civil Surgeon A. W May, Civil Surgeon P W James Civil Surgeon H. J Crossley, and Surgeon Captain T Moir, Imperial Yeomanry

Army Nursing Service —Superintending Sister Mrs J A. Gray, Superintending Sister Miss M Russell, Sister Miss M. C S Knox, Sister Miss C H. Keer, Sister Miss H L. Neale, Sister Miss E J Martin, Sister Miss G E Saunder, Sister Miss A. A Murphy, Sister Miss A. C L Anderson, Sister Miss A. R. Rose Innes, and Sister Miss A. E Tait.

Army Nursing Service Reserve —Sister H. C Luckie, Sister L Mitchell, Sister G Black, Sister A F Bedwell, Sister J Creighton, Sister C M Jones, Sister G Roberts, Sister E M. Monck Mason, and Sister J Halliday

Nursing Sisters (various colonies) —Superintendent M Rawson (Victorian), Sister Isobel Ivey (Victorian), Sister M S Bidsmead (Australian), Sister D Peiper (New Zealand), and Sister A. V Pocock (New South Wales)

In one of the earlier paragraphs of the despatches Lord Kitchener says 'I well understand that the accompanying list, which is in continuation of the other lists submitted periodically by me, of departmental, staff, and regimental officers who have in my opinion rendered exceptionally good service during the campaign is incomplete, and that notwithstanding all my care there must necessarily be a proportion of officers omitted who have rendered equal, or even better service than those who have been mentioned. This, however, is the fortune of war and will, I am sure, be well understood by the army I have been so proud to command.

THE LATE WAR.

We notice elsewhere the last of Lord Kitchener's despatches on the war in South Africa to which probably many medical officers among other people, will turn to see if their names are mentioned in it. We do not think that officers of the Royal Army Medical Corps will be disposed to think, considering the duration and all the difficulties of the late war that praise and rewards have been bestowed too lavishly upon their branch of the service.

Now that the war is a thing of the past the Boer generals and others are free to speak and they have touched upon some interesting points in the course of their speeches. General Meyer for instance has stated that the Boers never had more than 50 000 men under arms in the field at one time. It is very noteworthy, considering the amount of enteric fever that prevailed among the British troops that the Boers, practically speaking escaped that disease According to what General Meyer is reported to have said they had relatively little sickness of any sort and as far as his knowledge and experience extended, no enteric fever whilst on the veldt. They seem for the most part to have been without ambulances and to have had recourse when sick to some simple vegetable drugs called veldt medicines It is not at all uncommon, of course for the native population of a country to have a relative immunity from the sickness—typhoid fever for example—affecting new-comers or an invading army Still General Meyer's statements are interesting and instructive in their way Dr Johann Reinecke who acted as surgeon to the Boers during the war made his surgical experiences in South Africa the text of his dissertation on the occasion of the degree of M.D being recently conferred upon him by the University of Berlin His dissertation although practical and interesting did not teach anything particularly new to military surgeons. It inculcated the advantages of the *noli me tangere* principle and the application of antisepsis to gun-shot wounds and gave illustrations of the stoical fortitude of the Boers which made them the best of surgical patients.

ROYAL ARMY MEDICAL CORPS EXAMINATION

The following is a list of successful candidates at the recent examination in London —

Names.	Marks	Names	Marks
A. B Smallman	626	C. A. J A Balck	540
P Davidson	623	G W Smith	540
W F Tyndale	621	J M H Conway	536
W F Ellis	609	S. M. W Meadows	535
J McKenzie	602	J W S Seccombe	534
A H. Hayes	590	H. V Bagshawe	529
H J Crossley	587	C. V B Stanley	520
N D Walker	584	D S Skelton	519
W B B. Taylor	573	H G S Webb	516
R. Storrs	568	W W Browne	510
G T Collins	556	F L. Henderson	510
F A. H Clarke	554	N E. J Harding	500
G A. K. H Reed	548	W D C. Kelly	500
R L. V Foster	547	R Rutherford	499
R. B Ainsworth	542	W C. Rivers	493

CIVIL SURGEONS AND THE WAR GRATUITY

We have been asked by several correspondents whether the war gratuity will be given to Civil Surgeons who have served with the troops in South Africa. Civil Surgeons do not come within the category of those for whom the war gratuity is provided in Army Order 5 1901 and they are therefore not entitled to the gratuity It should be remembered however that all Civil Surgeons employed under contract are entitled to a gratuity of two months pay for a year's service, with an additional gratuity for each completed period of three months service beyond the year

MEMORIAL TO OFFICERS AND MEN WHO FELL IN THE LATE WAR.

On July 27th a mural tablet in coloured alabaster bearing the names of officers and men belonging to Guildford and neighbourhood who have fallen in the late war was unveiled in Holy Trinity Church Guildford, by Mr Brodrick Secretary of State for War The list includes the names of Captain M. L Hughes R.A.M.C killed at Colenso mentioned in despatches and Surgeon Lieutenant-Colonel W Wellington Lake, in charge of Hospital at Bloemfontein, where he died.

THE MAHMED WAZIRI DESPATCHES.

The following members of the Indian Medical Service are mentioned for services in the Mahmed Waziri campaign Major Ker Captain Cox, Lieutenant Pelle and Lieutenant Fry

Her Majesty the Queen will distribute the medals to the members of the staffs of the Imperial Yeomanry Hospitals who served during the late war in the gardens of Devonshire House, Piccadilly on Monday August 11th at 4 P M

The prizes won by the surgeons on probation who were successful at both the London and Netley examinations were presented on July 29th by Lord Roberts at the Royal Victoria Hospital, Netley

DIPHTHERIA AND ITS TREATMENT AT COLCHESTER.

To the Editors of THE LANCET

SIRS,—In your issue of July 26th p. 246 some statements are made by Mr H. Whitby reflecting on myself and in a letter in your issue of July 19th, p 182, there is a letter from Dr G Brown on the same subject—diphtheria at Colchester—which calls for some remarks. Mr Whitby states that three of a family were attacked with sore throat and exhibiting all the signs of diphtheria, that the medical officer of health took swabs from two of the family and declared the results to be negative. *I have looked through* my list for this year and the only case which tallies with the description in any way is that of a family where four swabs were taken where diphtheria germs were found in three out of the four These cases were notified accordingly and admitted to the infectious diseases hospital. The only other case where more than one swab from a family were examined for him occurred in April when I had two swabs marked Mrs. J and Mrs' or 'Miss J " I could not make out which. No diphtheria germs were found in either of those, but they were swabs taken by Mr. Whitby and sent with no comment whatever and so can hardly be the swabs referred to Since March 22nd I have examined swabs for Mr Whitby from six, not four houses in not one of these have diphtheria germs been found. What the symptoms were I know not, as help of that sort is never given by him but in one case at least the patient, when visited by the sanitary inspector on the day of notification, was up and about and opened the door for him. Mr Whitby seems to object to the discovery that none of these cases were cases of diphtheria, using the word in the restricted sense in which it is now usually employed. *A priori* one would have thought he would have been only too glad to find that this was the case No subsequent case of diphtheria arose in connexion with any of these cases and I take it none of them developed later any of the characteristic sequelæ which otherwise would surely have been noted With regard to the comments on antitoxin it would be interesting to know who it is who praises the remedy as infallible since anybody who knows anything at all about the matter must be well aware that it is far from such having of course no curative power whatever after a certain period. It would also be interesting to have full clinical details of the two cases—of albuminuria, and of albuminuria and bronchitis, with the reasons, if any for connecting the symptoms with antitoxin. I may state that the majority of the cases arising here have been treated at the infectious hospital, and that since I have had charge of the patients there not a single person has ever left with even a trace of albumin present. Mr Whitby finally thinks that it is grave that he should not be permitted to have an opinion other than that manufactured *for* him but surely it is a much graver matter for his patients not to have the benefit of the treatment which has been shown to result in the least percentage mortality to them

Coming now to Dr Brown's letter he states that in July 1901, and subsequently diphtheria in Colchester assumed a less virulent form I am not for a moment prepared to accept this statement. True I did not see many of the cases before the middle of July, but in the same way Dr Brown did not see many of the cases after that date. He certainly never examined *any* of them. For a time he used to accompany me when visiting the hospital after July 17th when I took charge of the treatment of the patients Such patients as he saw at a distance then had *often* already been treated, 24 hours or more, previously with antitoxin Before long he gave up coming to the hospital at all. I cannot see how he can have divined the condition of the patients after this—patients whom he never saw at all There certainly were a number of bad cases among them and quite a sprinkling of exceedingly serious cases The most conclusive evidence on this point is afforded by the case mortality of patients treated outside the hospital. Before July 16th there were 37 cases with a percentage mortality of 10 8 per cent., after, 48 cases with a percentage mortality of 14·5 per cent., during which time the disease is said to have grown milder I cannot quite make out the meaning of some figures which follow, but the broad fact which *to me seems to stand out conclusively* is this Before July 17th antitoxin was given to some cases by Dr Brown—not to others It seemed to me that he used it for the bad cases, and he certainly did not seem to be cognisant of the fact that to be of any use it must be employed early, since he did not use it on admission but at some period, even as late as 10 days, after Reliance was placed chiefly on the use of a spray of dilute lactic acid Now, as Dr Graham Smith has pointed out in the *Journal of Hygiene* for April of this year, the mortality in the first half of the year among cases so treated was 25 9 per cent. In the latter half of the year, when antitoxin was systematically used on admission, the percentage mortality was 5 8 per cent. If the cases for this year be added the total up to date (including four cases which arose and were treated in the isolation home) amounts to 190, the mortality being 6 3 per cent All the cases which have died since I have had charge of the patients have been late cases I have not yet seen an early case treated with antitoxin become worse and die Several of the cases which died were moribund on admission, one case dying within an hour of admission. The statement as to ciliated epithelium has already been commented on, and the deduction founded on it, *re* nurses catching the disease, therefore falls to the ground As epidemics did not occur in the previous years, a large staff of nurses was not employed and there was naturally less chance of a number becoming infected The first nurse was attacked just before I commenced visiting the hospital. Dr Brown states that [illegible] of diphtheria later caught scarlet fever and that many [illegible] died Personally, I have only had one such case [illegible] a statement also that it was remarked that the [illegible] would be extirpated in six weeks from Sept 1st when [illegible] laboratory had been set up I do not know [illegible] of this statement but I well remember that [illegible] who was directing the arrangements, told Dr [illegible] myself at our first interview together that the [illegible] be wanted, at any rate, till Christmas [illegible] to remark on the value of bacteriological [illegible] and isolation of infected contacts which Dr [illegible] of little or no avail.

[illegible] the laboratory was got into working order the [illegible] reopened, though diphtheria was rife and the [illegible] was at hand. In spite of this the number [illegible] diminished through the autumn Secondly, [illegible] a girl was brought to me because she had a [illegible], she went to the Central School for Girls [illegible] germs were found in this case The school mistress [illegible] asked then to give me the names and addresses of every child away from school on any pretext every morning All these cases (except such as accidents, &c.) were visited and where it seemed requisite swabs taken and examined. In all six definite cases (and one doubtful one) were found in which diphtheria germs were present Of these cases five showed some further symptoms or signs of diphtheria and were actually notified, four by myself and one by another practitioner Of course, all these patients were kept from school with their brothers and sisters and as many as possible were removed to the home. No further case up to the present has arisen in this school Thirdly, a short time before July 8th I heard of a case of diphtheria in a family some of the members of which attended at Shrubend school, in a village about a mile outside the town The house was outside the borough boundary but I had a swab sent to me and found plenty of diphtheria bacilli present, a second case arose close to this one and was fatal. I asked the schoolmaster to let me know once of any case of sore throat among his pupils in my district On the 8th there was such a case reported which turned out to be a well marked case of diphtheria. I now *started visiting the school myself every morning* The school was kept open, every child who failed to put in an appearance at school-time was visited, and if ill in any way swabbed During the next four days 11 cases of diphtheria were thus discovered. By the means employed the infected children were eliminated from the school, together with others of their family, and no child was ill for as long as 24 hours without being injected with antitoxin, except in one case where on account of the parents I was obliged to delay, but was allowed to use antitoxin in the evening No further death occurred, though four at least of the cases started in a virulent fashion—in two the nose as well as the throat being affected After July 12th no further case arose which could be connected *with the school* bar *one*, which *might* have been *contracted* at school, though I fancy it was not so Besides these cases there were a few children outside the borough attacked and a good many children infected, but not ill, were discovered and as far as possible isolated In the houses discovered at first to be infected six other cases subsequently arose, but no new centres have come to light, the last case notified being on July 22nd. Fourthly, the examination of patients bacteriologically before discharge from hospital was very effectual in preventing "return" cases In about six weeks, of which I have record, before the system was employed there were four such cases In the whole period from that date till to-day I know of only two doubtful cases. Finally, I should like to note a case which Dr Graham Smith has commented on at length in the *Journal of Hygiene* for April, 1902 This patient suffered from a bad sore throat, she was seen later by Dr Brown, who did not consider that she was infectious and took no swab Subsequently, 15 cases arose which can apparently be traced to this case, and several of these cases proved fatal.

I am, Sirs, yours faithfully,
ED CHICHESTER, M B Lond.,
Acting Medical Officer of Health of Colchester
Colchester, July 28th 1902

To the Editors of THE LANCET

SIRS,—I am surprised that Mr E C Bousfield should feel a difficulty in believing that Dr G Brown of Colchester is in earnest when he expresses doubts as to whether the antitoxin treatment is the best treatment for diphtheria and that you, Sirs, should apologise for allowing your columns to be used by persons who, to use Dr Brown's expression, "do not bow the knee to Baal." The way in which the antitoxin treatment has been praised, idolised, and worshipped certainly justifies the comparison, and it makes the comparison still more suitable if the priests of "Baal" proceed to lash themselves into a fury because the divinity of their idol is
challenged You say, Sirs, that the treatmen[illegible] been
accepted by practically the whole medical worl[illegible] ble,
and no doubt that is so But was not the tuberc[illegible] ent
so accepted within the shortest memory? Be[illegible]
advocates of the [illegible] n treatment are n[illegible] h
claiming that it i[illegible] le treatment [illegible] a
"cure" for diph[illegible] edy which [illegible] to
cure," as Mr B[illegible] it. Now, [illegible] a
statement is so r[illegible] of actual
a fact. I hav[illegible] in saying
treatment is n[illegible] dir
not think it [illegible] for
available [illegible] d
final in the
viction, and

new treatment to prove its efficacy Therefore if Mr Bousfield will undertake to maintain the title of diphtheria antitoxin to canonisation as a ' cure,' I will, for the sake of argument, take the part of 'devil's advocate" and dispute its right to the title

I am Sirs, yours faithfully
HUGH WOODS
Highgate N July 27th 1902.

To the Editors of THE LANCET.

SIRS,—In my last letter I left Dr G Brown's statistics alone, having no materials for criticism these have now been supplied me. In 1901 (up to July 16th) 89 patients suffering from diphtheria were removed to the infectious diseases hospital at Colchester of these 18 had antitoxin before admission and one death occurred among them. Of the remaining 71 no less than 22 succumbed. Comment seems unnecessary Moreover the statistics given by Dr Brown make it abundantly clear that in many of the cases said by him to have been treated with antitoxin the remedy was used as a last resort, and figures based on such cases are absolutely worthless.

I am, Sirs yours faithfully
EDWARD O BOUSFIELD
Old Kent-road S.E. July 29th 1902.

THE MEDICAL SERVICE OF THE MERCANTILE MARINE

To the Editors of THE LANCET

SIRS,—I have not seen the previous correspondence on this subject, but the letter of Dr A. B Blair in your issue of July 12th, p. 111 rather surprises me. He thinks that these medical officers are well off because they get £10 a month in pay are well fed, see much of the world, and are not too hard worked. He says that the position is never in danger of being lowered. £10 a month! This is the pay of the second officer the third engineer and the second steward. All these men are as well fed as the surgeon they have the same chance of seeing the world and are not too hard worked Does Dr Blair mean to say that a medical man who is paid at the same rate as these subordinate officials is paid in accordance with his position? If he does, I do not agree with him for I have a much higher opinion of the value of medical services.

In my opinion the surgeon holds the most responsible position of any on board If anything very serious occurs he must depend on his own knowledge alone, whereas the captain and engineer have their mates to consult with, and these are generally as well able to meet the emergency as their chief But the surgeon has no one to consult with. And that very serious cases do occur at times I know by experience. Socially the surgeon is nowhere. When the executive officers mess in the saloon they take the head of the tables, the surgeon and purser being placed at the foot. If the surgeon gives an order to a sailor or a steward to move a deck-chair he may be told by the man that he takes his orders from the mate or the steward. In many vessels his state-room is also his consulting room and his dispensary and this room is no larger than the state room allotted to other officers. In one ship I sailed in this was the case It was placed in the alley way beside the engine-room and next to the water closet. As the bulkhead between the room and the water-closet was not water tight the floor was constantly wet and so I condemned it. After a struggle I got a room in the saloon but though there were plenty of empty rooms the one I got was the worst, right over the propeller Yet the captain of this ship had two fine rooms and the chief steward had a room in the saloon vastly superior to the one I got, and, indeed it was only by threatening to bring the matter before the Board of Trade that I got another room. Dr Blair says that the position is never in danger of being lowered in the eyes of the passengers or crew Does he mean because it is so low already for it is a fact that passengers and officers look with more or less of scorn on the ship's surgeon firstly because he is considered as nobody on board and, secondly because he takes tips. It is this taking of tips which is so disreputable so degrading in the eyes of the people and which makes the position of the surgeon appear so contemptible in the eyes of all. For a steward to take a tip is nothing he is only a servant-man, but a surgeon is supposed to occupy the position of a gentleman—that is, of the man who tips. Yet I have met many surgeons who could see no harm in it and who gladly took the tips and tried to call them fees. But they are not fees any more than are the tips to the steward fees, for the passengers know that these men are paid for their services and that to tip them is optional I certainly have noticed that many of the steamship doctors are an abject class. I believe it is due to the fact that they are afraid of losing their tip Probably the same men would be abject on land also but, then very many medical men are very abject creatures before their good-class patients.

Dr Blair says that £10 a month is sufficient pay but is he aware that some of the lines only pay £6 a month and those in steamers crossing the Atlantic in winter as well as others? And in THE LANCET of last week is an advertisement offering a surgeon £5 a month to go to Australia and back I think that the profession could alter all this if it would act. If the schools would strongly impress on young men to avoid these steamers unless the conditions were suitable the steam ship companies would soon consent, as they must have surgeons. And the conditions I would insist on are these (1) that the surgeon be paid a minimum salary of £10 a month for which he will attend the crew and steerage passengers (2) that he be at liberty to charge fees for attendance on first- and second-class passengers, and (3) that he have a state room in a suitable place for himself quite distinct from a consulting room or dispensary These conditions would put no strain on the steamship companies and they would put the surgeon in a right position on board in the eyes of all.

I am Sirs, yours faithfully
J OGILVIE
July 23rd 1902.

INSANITY AND THE DEATH PENALTY

To the Editors of THE LANCET

SIRS,—I have read with interest Sir W T Gairdner's letter in your issue of July 26th, p. 242, but I cannot agree with him that any idea of vengeance is present in the punishment meted out to the criminal by the State. Vengeance is entirely a personal emotion but the State knows no such passions being impersonal and in a strictly impartial manner enforces by suitable punishments the laws it has enacted If the punishments do not have the desired deterrent effect they may be useless, but I submit that they cannot be regarded as State vengeance on the criminal. It is true that the poet speaks of the wild justice of revenge," because the act of the vengeful man and that of the State may equally deter from crime but the motives of the act in the two cases are altogether different. With regard to verdicts, Guilty but insane, they would be contradictory under the present law If a criminal is insane in the legal sense he cannot be guilty in the eyes of the law That the legal definition of insanity in McNaughton's case is by no means in accordance with our present knowledge of mental disease may be readily admitted, but none the less I am one of those who do not think that the public safety will gain by modern views of mental pathology being permitted further to diminish criminal responsibility

I am, Sirs, yours faithfully
M. GREENWOOD
Hackney-road N.E., July 26th, 1902.

OBSERVATIONS ON DIET

To the Editors of THE LANCET

SIRS,—I feel I owe Dr Forbes Ross an acknowledgment for his admission that he would not insist upon a full and generous diet in the case of every aged patient likewise for giving me an opportunity of saying that for some old people I would regard such a diet as suitable.

Dr R. H. Perks's earnest letter I have read with great interest. He who eschews animal food for ethical reasons cannot but command the admiration of all serious men. In seeking after truth we must not, however allow our vision to be blurred by our feelings, humane or otherwise but endeavour to look at facts as they are, however repugnant those facts may seem to us.

1. I have not contended as Dr Perks appears to assume, that man is by nature purely carnivorous but simply that he is largely so. Dr Perks cites authorities who maintain on anatomical grounds that man is essentially frugivorous, but others equally eminent contend that the anatomy of his digestive system proclaims him in large degree carnivorous. I will therefore waive the anatomical argument—although

to my mind it is all in favour of this latter view—and appeal to another line of reasoning If it can be shown that from the time man emerged from an ape like being down to the agricultural era—that is to say, during an immense period of his evolutionary career, for from the standpoint of evolution the *period of agriculture began but* as yesterday—he subsisted largely on animal food, we may safely conclude that he is naturally to a large extent carnivorous And this, I believe, can be shown It is known that the man like apes are not purely vegetarian, but that they eat birds, eggs, and insects of all sorts Now if these creatures supplement their vegetable diet in this way the strong presumption is that man's ape like ancestor did so likewise, and that from this anthropoid period of his evolution down to the agricultural era he was largely an animal feeder is as certain as anything can well be, for how otherwise could he obtain the necessary supply of proteid? Certain it is that the most primitive type of man now living is wholly unable to maintain himself on a diet derived solely from the uncultivated vegetable kingdom, those tribes which do not cultivate plants for food are compelled to resort largely to animal food So far as my researches go—and I have taken pains to get at the truth in this matter—there is no part of the world where man can subsist entirely on wild uncultivated plants The view that there are certain luxuriant regions where unaided nature yields man an abundance of nutritious food all sufficing for his needs is altogether erroneous Not only do wheat maize, potatoes, yams, carrots, peas, beans, lentils, and the like need assiduous cultivation if they are to yield a copious supply of nourishment (which, moreover, is only available after cooking, an art which is, phylogenetically considered, of quite recent date), but the like is equally true of the fig, date, banana, cocoa nut, to say nothing of the sugar cane, sago, palm, and a host of other nutritious plants belonging to the tropics

2 Dr Perks does not make it clear whether the flesh abstainers to whom he refers abstain also from milk, butter, cheese, and eggs If they do not, then I must repeat my charge that they are accessory to the slaughter of animals Dr Perks refers to this as a minor difficulty in the way of those who are desirous of abolishing or lessening the slaughter of animals for food. I protest that this is no minor but a major difficulty Farmers cannot sell eggs and milk at a profit unless they slaughter the bull calves and cockerels and sell them or use them for food. To be consistent, therefore he who abstains from flesh for ethical reasons should abstain also from milk, butter, cheese, and eggs, unless he can be assured that the producers of these articles do not allow the bulls and cockerels to be slain for human consumption.

3. While I contend that man, having evolved from the anthropoid on a diet that has been largely an animal one, is therefore by nature in large measure carnivorous, I must not be understood to imply that he is for ever doomed to remain so The great difficulty in regard to a strictly vegetarian diet is its deficiency in proteid, and, as I pointed out in the last of my four articles,[1] the consistent vegetarian should aim at extracting from the vegetable world suitable proteids, so as to be able to fortify his vegetable foods with them and thus make good that deficiency If he proceeds on these lines I see no reason why his humane dream should not be realised I am, Sirs, yours faithfully,

Wimpole street, July 27th 1902 HARRY CAMPBELL

THE MIDWIVES BILL

To the Editors of THE LANCET

SIRS—Although it may appear late in the day to discuss the Midwives Bill with public utility, seeing it has become law, nevertheless the letter signed by the President and chairman of the Association for Promoting Compulsory Registration of Midwives did not appear until the day on which the measure was passed—too late, I presume, to influence the debate in the House of Lords I must beg of you therefore, not to allow such a letter to remain unchallenged—'Audi alterum partem' Although it is difficult amidst the chaos of voluminous printed matter extending over years to place one's finger on chapter and verse, I venture to state and am open to correction, that the promoters of registration until within a very recent period distinctly gave out that the object of their measure was simply to ensure for the poor a class of trained midwives amenable to law and hence to prevent any save those registered from calling themselves midwives, but that they did not desire to prevent the poor helping one another in *cases of emergency, or need I say that this was the original* purport of the scheme and this they asked and nothing more? It began, however, to dawn upon the promoters under more mature consideration that a measure of this kind would be more or less futile, as was clearly pointed out in the earlier stages of the discussion, because it is evident that the Gamps being regardless of the title "midwife" would be at liberty to pursue their craft as heretofore and consequently the promoters have now been driven to adopt the "neck or nothing" system of discovering the quickest means of exterminating the Gamps from the face of the earth, and that is by rendering it illegal for any but registered midwives to attend for the purpose of gain It will be interesting, therefore, to watch what the poor in agricultural districts will do cut off from their succour and supply of Gamps, because, after all said this much maligned class have borne the heat and burden of the day for generations and have occupied a position on the obstetric field that no frantic parent, sister, or emotional neighbour could act as a substitute, in spite of what the President and chairman of the association in question say, or to quote their words "It is often forgotten that the word 'habitually' in the clause leaves a wide margin for freedom of action in cases of emergency or for the individual preference of patients" Pray, Sirs, what is the use of leaving a wide margin after the Gamps are exterminated and there is nobody to act?

Both the Lord Chancellor and Home Secretary appeared to take the view I now enunciate and it is difficult to follow the reasoning of the President and chairman of the association when they advocate in reply to the Lord Chancellor's suggestion "that those who drew up the Bill had in their minds large centres of population and had not considered the case of thinly populated districts where trained assistance would be hard to get," and yet they argue this as a reason for registration, but who can support a midwife located in a lonely country village? There is an old saying that the Lord preserves babies and drunkards, and to these might be added parturient women, because it is certain that in the process of nature accidents *rarely* occur through the attendance of an unskilled midwife—at least this is my observation after many years—and I venture to state that the loss the poor will sustain from the extermination of the Gamps will far exceed anything that may accrue from registration.

I am, Sirs, yours faithfully

Peckham, S E, July 29th, 1902. CLEMENT H SERS.

INTESTINAL SAND

To the Editors of THE LANCET

SIRS,—Dr C H. Bedford in his Note on a Case of "True" Intestinal Sand in your issue of July 26th, 1902, p 215, alludes to the three cases of intestinal sand mentioned by me in the discussion which followed the reading of the paper by Sir Dyce Duckworth and Dr A. E. Garrod[1] as having occurred during my 10 years' tenure of the appointment of surgeon superintendent of the European General Hospital, Calcutta, and regrets that there is nothing to show that these were genuine examples of "true" intestinal sand, "as apparently there was no chemico microscopical examination made in any of them."

My object in making my observations on the subject was not to prove that mine were genuine cases of "true" intestinal sand (that, I hoped, would have been accepted without question), else I would have stated, as I do now, that the samples were subjected to frequent microscopical examination by myself and the other members of the staff of the hospital, that one specimen was examined chemically by the then professor of chemistry of the Medical College, Calcutta, and that another was examined by the late Mr Wood Mason superintendent of the Indian Museum, Calcutta. The specimens were identical with those submitted to the Royal Medical and Chirurgical Society by Sir Dyce Duckworth and Dr Garrod Dr Bedford may therefore be satisfied that the three cases noted by me were genuine examples of true intestinal sand. I did not mean it to be inferred that the affection was commoner in India than in England because I had met with three cases in ten years. What I said was that it was probably more commonly *observed* in India than in England because of the routine practice in Indian hospitals of washing the stools in all intestinal cases. This will naturally lead to the more frequent discovery of sand in cases in which its existence is not suspected Of this I had an example during the present month in a case of pernicious anæmia in the person of an Armenian who had spent all his life in Calcutta whom I had an opportunity of seeing with Mr C. Andrews of West Kensington and Dr E. Lawrie lately of Hyderabad. Each of his motions when washed betrayed the presence of true intestinal sand in small quantity There were no symptoms referable to the sand and its existence would not have been suspected or discovered by a casual observation of the stools without washing This patient had been for many months on a diet consisting largely of milk and exclusive of vegetables and fruit except grapes, and therefore conforms with Dr Bedford's suggestion as to the probable cause of true intestinal sand but I find in an old case book that one of my Calcutta patients who consulted me privately before going into hospital had been living an ordinary life on mixed diet. His dietary is detailed in my notes and I find it specially stated that he had not eaten tinned Californian fruits for three months which will show Dr Bedford that I was well aware of the conditions under which false intestinal sand is most commonly formed pears not being usually available in India except in that form. I am Sirs, yours faithfully

CIDER AND GOUT

To the Editors of THE LANCET

SIRS,—Under this heading the question is asked in THE LANCET of July 19th p. 182, by Dr T Dobson Should the gouty drink cider? My answer unhesitatingly is, Yes but he must be careful what cider he drinks Unfortunately the public has a preference for sweet bottled cider and this taste has been fostered by makers and dealers generally and the result is that at the present time there is hardly any bottled cider in the market that is wholesome and fit to drink more especially by those who have a tendency to gout or to rheumatism. The bottled ciders (and by cider I include perry) are all filtered and faked up for the market and I would warn anyone not to drink very freely or regularly of them. If he has any tendency to gout or to rheumatism it will be certain to develop an attack and if he has none already it will probably cause it.

Irrespectively of the different sorts of cider some being better for certain constitutions than are others all ciders when made should be unfiltered and allowed to pass through the full process of fermentation This is the essential point, and the bottled ciders now to be bought from the very best makers are all filtered and their fermentation interrupted. In this way a sweeter and more brilliant looking fluid is the result. If fermentation is allowed to go on and no filtering carried out a pure, wholesome beverage of a dry nature and bright enough in appearance for most people is obtained. The sugar is thus got rid of and if the cider be kept in the cask undisturbed from its sediment it will in three or four months be as bright and clear as a spirit and should be bottled if necessary about the time that the trees bloom in the following spring Cider treated in this way may be drunk with great benefit by gouty or rheumatic people and it is, I think, one of the very best beverages for them.

I am, Sirs, yours faithfully

Winchcombe, Gloucestershire July 25th, 1902. WILLIAM COX.

MEDICAL PRACTITIONERS AND THE HOME OFFICE

To the Editors of THE LANCET

SIRS,—I desire to call special attention to the actions of the magistrates and medical practitioners of Bungay as narrated and commented upon in your columns in connexion with your remarks on the attendance of the members of the British Medical Association when the reconstitution scheme was under consideration.

Mr Ritchie has no doubt recently been primed with Obstetrical Society literature in connexion with the Midwives Bill His remarks on the question of the propriety of the conduct of the practitioners of Bungay can be explained quite easily if The History of the Work of the Obstetrical Society in Relation to Midwives Registration " (published 1895) be read. No one reading this without a full knowledge of all the facts of the case could fail to believe that the ordinary general practitioner is certified as a scurvy fellow by those who claim that they are considered generally to be the most qualified to form an opinion Mr Ritchie only repeats what can be found in the pamphlet to which I allude. The mischief which has been done to the great mass of the profession by the Obstetrical Society will manifest itself for years quite outside the result of its achievement in legislation that legislation will do no harm The conduct and the utterances of those who ought to know better have weakened the profession and have shown up the weakness in its organisation to the world at large. Who can blame a politician for using the weapon placed in his hands by members of the medical profession against that profession? The remedy which I have for years advocated is the manufacture of a sufficient political organisation The British Medical Association now possesses a framework for such Will its members consent to apply business principles in the use of the frame?

In the first place the members have to raise their courage to spend both money and time and to use each one his own powers of business if a successful campaign is to be fought. It is most devoutly to be hoped that every practitioner will cease to regard medical politics as a subject derogatory to the dignity of the profession. That position is the cult of the mere Brahmin If medical practitioners will realise once and for all that the interests of the mass are his own personal interests then progress will be made The Brahminical cult will then be a thing of the past. So long as each practitioner belongs to a sect which looks askance at other sects the position of affairs is hopeless and must remain so I am Sirs, yours faithfully

Ha field July 29th 1902. LOVELL DRAGE.

PERITYPHLITIS

To the Editors of THE LANCET

SIRS,—Dr W J Tyson has in his letter referred to an operation performed by me at Guy's Hospital some years ago As the question of priority is of interest to your readers it might be well to give you exact dates In doing so I in no way wish to detract from the merit which belongs to Sir Frederick Treves. The case is fully recorded in the Transactions of the Clinical Society for the year 1885 vol. xviii. p 285, where it will be found that the operation was performed on August 24th, 1883, the account being read on May 8th 1885. As stated in that paper whatever credit is due for having suggested at this date an operation for the relief of recurring attacks of pain in the cæcal region must be due to Dr Mahomed. He was impressed with the great fatality caused by delay in opening the abdomen and when we were together appointed to the staff of Guy's Hospital in January 1882, we decided to operate early in acute obstruction and allied conditions The frequency with which cases of peritonitis and other cases resembling obstruction proved to be due to sloughing of the appendix led us to study the diseases of this body

Those who remember Dr Mahomed will appreciate the following story In order to gain a fuller knowledge of the subject I went through the post-mortem records of cases of typhlitis These had been made by Wilks Moxon and Fagge The admirable drawings of Moxon illustrated the whole pathology of acute appendicitis and one thought one had gained a point or two in diagnosis and treatment. Mahomed one day bursting in upon my retreat in his well known energetic way said Come along Symonds if you study these cases any longer you will become like —— [a now well known baronet] and not make a diagnosis at all I have a case of acute obstruction and want you to operate at once." However the case seemed to me very clearly one of acute appendicitis with general peritonitis operation confirmed this view and served to redouble Mahomed's enthusiasm. Soon after this the case Dr Tyson referred to occurred. It was that of a young man who had had many attack of colic in the iliac region where a hard rounded nodule was to be felt in the position of the appendix. Mahomed called me to the case and suggested that there was a concretion in the appendix and that it might be removed. In planning the operation we differed as to method. Mahomed wished that an incision similar to that for ligaturing the external iliac artery should be made and the peritoneum raised up, he expected the appendix would be shut off by adhesions and might therefore be opened from behind without entering the general cavity Personally I advocated an incision from the front and removal of the appendix. Mahomed's plan was successfully carried out and the concretion, covered with a laminated capsule of carbonate of lime, removed. As a matter of fact, subsequent experience has shown that concretions having a calcareous capsule lie outside the appendix, having escaped in some acute attack. There will be found an excellent water-colour drawing of this—the first concretion ever removed—in the Transactions referred to, and in the same paper the question of operation is discussed and other interesting points When Fagge lay ill, though engaged on his book, I took this concretion for him to see and related the case. He examined it with interest and, handing it back, said, as he looked in that pleasant quizzical way he had, "Yes, Symonds, it is interesting, but I don't suppose it will ever be done again" Unfortunately, poor Mahomed—a veritable pioneer—died in 1884, and it was long before another opportunity occurred to me of dealing with an appendix in the quiet period as there were few in those early days so ready to advance as was Mahomed.

I am, Sirs, yours faithfully,
CHARTERS J SYMONDS

Portland place, W, July 29th, 1902.

THE ANTI-MEDICAL BIAS

To the Editors of THE LANCET

SIRS,—Without wishing to disagree with the main drift of your annotation, "The Anti Medical Bias,"[1] may I be allowed to take exception to its penultimate sentence? Dr Veressaief is certainly not a heterodox practitioner Throughout his work, "Les Mémoires d'un Médecin," he repeatedly asserts his respect for his art and for its professors In one place he even advocates an increase in the practice of vivisection and can only be called an antivivisectionist in the sense that he condemns those long ago discredited experiments on living people common in the "eighties" of last century His book is brilliant, full of pathos and observation, and manifestly sincere, but the publication of *ad captandum* confessions which are sure to fall into the hands of the nervous and the wrong headed, is manifestly indiscreet

I am Sirs, yours faithfully,
FIAT JUSTITIA.

July 28th, 1902.

BIRMINGHAM

(FROM OUR OWN CORRESPONDENT)

Birmingham University

THE second degree congregation of the university was held in the Town Hall on July 19th. A large gathering witnessed the imposing ceremony, although general regret was felt at the absence of the Chancellor, the Right Hon Joseph Chamberlain, M P, whose place was taken by the Vice-Chancellor, Mr Charles Beale, who conferred the degrees upon the recipients An interesting address was given by the principal, Sir Oliver Lodge, D Sc., F R S, who directed attention to the rapid growth and development of the university, and in well chosen words alluded to the great services rendered by the Chancellor, which he described as the main factor in the progress which had been made. The statement that the university was thriving and showed every sign of vigorous health and the allusion to the formation of a representative council inaugurated by the students were received with acclamation Considerable interest was taken in the principal's remarks on the formation of the Faculty of Commerce the first dean of which is Professor Ashley The relative importance of this new departure in the teaching of the university will have to be decided by experience The Birmingham City Council has materially aided this portion of the scheme, the halfpenny rate yielding some £5000 a year to the university, while foundation scholarships should give a good start to such an important change in educational methods The bestowal of the degrees in Science and Arts and those of Doctors and Bachelors in Medicine was celebrated with enthusiasm. The school of medicine has reason to look with pride and hope upon the medical portion of the university teaching

The General Dispensary

Some important and valuable changes have been made recently in the staff of the General Dispensary, an institution conducting an extensive practice over a wide area. At a meeting of the governors held on July 21st the committee brought forward a scheme by which the scope of the consulting staff was considerably widened. Four physicians, four surgeons, two gynæcological consultants, and one ophthalmic consultant are recommended for appointment instead of the former plan of one consulting physician and one consulting surgeon The new officers are to receive fees for their services, in place of an honorarium annually given to the former staff of two officers It is considered that the alteration will bring the institution into closer touch with the hospitals of the city, and will enable the resident surgeons to select a consultant known to be an expert in the particular department of medicine or surgery covering the case in hand. If carried at the annual general meeting in February next the scheme will come into operation

Heavy Sentences for Illegal Practices

At the Birmingham assizes a druggist was charged with illegal practices in procuring abortion in a case which nearly terminated fatally It was shown in evidence that for a considerable length of time he had been in the habit of using instruments and administering noxious drugs to women who applied to him for assistance. A sentence of seven years' penal servitude was passed. This should certainly serve as a preventive of such practices which are common in large centres and which often result in disastrous effects to health. A remarkable case of the same kind where the offender was a druggist was tried at the Staffordshire assizes held this term The prisoner had been convicted 20 years previously of a similar offence which resulted in the death of a girl, for which he was sentenced to be hanged The sentence was commuted to penal servitude for life On being let out of prison he committed another similar crime He has just been sentenced to penal servitude for life again, and as his age is 74 years he will probably have no further chance to pursue the evil bent of an ill balanced mind

July 29th

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

The Meeting of the British Medical Association.

THE meeting of the British Medical Association promises to be very successful so far as numbers go, and the Manchester medical men, who have a good character for hospitality, are doing all they can to make the gathering agreeable Breakfasts, luncheons, garden parties, and receptions will keep the members of the Association industriously occupied while the intellectual food provided is abundant and suited for all degrees of mental digestion So far as a brief visit to the Owens College can indicate the arrangements are very complete and well organised, but upon this point and all others connected with the meeting your various special correspondents will no doubt inform you The weather is somewhat unsettled, but there is a fervent hope that it will redeem Manchester from its popular character not always deserved, of being a wet place

The Manchester Infirmary

The *City News*, a weekly local paper, in its issue of Saturday last begins an article as follows "After a quarter of a century of considering and re considering the important question of the rebuilding of the Manchester Royal Infirmary is just where it was at the beginning" This is the result of the rejection of the scheme put forward by the infirmary board at the meeting of the trustees held on July 21st The majority against the scheme was about three to one, but a poll of the whole of the trustees is to be taken by voting papers which were issued on July 26th and must be returned by

---

[1] THE LANCET July 26th 1902, p 234

August 2nd when the question of rebuilding on the present site will be decided one way or the other But the more the plans are considered the worse seems the case for rebuilding No fault is to be found with the architects who have shown considerable ingenuity in attempting an impossible task. The plans show lofty five- or six storeyed buildings with far too little space between them, so that they would darken each other leaving most gloomy and insufficient intervals. The open space round the present building is encroached upon appreciably, while part of the area almost inclosed by buildings is counted as open space although pretty well hidden and the air in it well boxed up. All this would bear fruit in the future in the unwholesome condition of many of the wards There was a strong feeling at the meeting in favour of the Stanley grove site, which 'is a quiet place, close to Whitworth Park, well removed from the thoroughfare and may be had for the asking' Although the Convalescent Hospital at Cheadle relieves the infirmary when the patients are fit for removal it is a great disadvantage that practically they are debarred at Piccadilly from ever sitting out of doors as some of them might do while at Stanley grove this would be quite possible and it would be in fresher air One member of the staff, in his earnest advocacy of retention of the infirmary on the present site, stated that Stanley grove was the foggiest place in Manchester but that statement may safely be taken as rhetoric. No doubt Manchester and indeed the district round is more subject to fogs in winter than is desirable, but they are as a rule quite as bad in the centre as in the suburbs and distinctly more pungent. But it ought not to be necessary to argue that air comparatively pure is better than the smoke laden dust-laden air of Piccadilly If the scheme for rebuilding is carried the limits of the institution will be fixed irrevocably No further extension can be made as the needs of the city grow, for grow they will while it would be quite possible on the larger site In to-day s papers a strong appeal is issued against the rebuilding scheme and in favour of the Stanley grove site, ' so generously offered by the Whitworth legatees if a better and cheaper site is not available, signed by Earl Egerton of Tatton, Mr R. D Darbyshire His Honour Judge Parry Sir Bosden T Leach Sir Anthony Marshall both ex Lord Mayors of Manchester and 12 leading firms of Manchester We can scarcely expect a better and certainly not a cheaper site than Stanley grove. The war of sites seemed to be almost over but perhaps it is only beginning

Hospital Sunday and Saturday Fund

It has been decided by the General Committee of the Manchester and Salford Sunday and Saturday Hospital Fund to distribute £7300 out of this year s collections among the 20 participating charities. The Royal Infirmary as the largest, receives £1301 and the Children s Hospital £919 The remainder is apportioned according to the provision made for the sick. Two homœopathic institutions receive £40 between them.

Accommodation for Lunatics

The asylum difficulty which is not a new one, came up again at the meeting of the Manchester board of guardians on July 23rd. In a letter to the Crumpsall Workhouse Committee Dr L. R. Lempriere, the assistant medical officer called attention to seven cases of lunatics in the wards which had been certified and ordered by justices for removal to an asylum, but on application being made at the asylums to receive them the answer was that there was no room. The chairman said it was thought that when the Winwick Asylum was opened *their troubles* with dangerous lunatics would be at an end. The clerk stated that another case had occurred and the patient was taken to the Prestwich Asylum but was refused admission for want of room. It appears that there are about 1200 cases at Winwick and there is room for more but they are only taken from other asylums and not from boards of guardians It was decided to send a memorial to the Asylum Board calling attention to the difficulty in which they are placed and requesting that steps should be taken to supply the deficiency It was stated that one patient who had recently died had been an inmate of the Whittingham Asylum for 65 years showing the care that was bestowed upon them and the healthiness of their surroundings." Some arrangement ought to be made to relieve the workhouses of their dangerous lunatics and to place them where they can be more safely housed

The Leech Memorial Fund Report of the Committee

The committee of this fund has presented its final report to the subscribers. The total amount received was £1305 3*s* 6*d* from 157 subscribers. The main object of the fund was to provide for the immediate endowment of the Leech Professorship of Materia Medica and Therapeutics in the Owens College and this was achieved by the payment of the sum of £1000 to the college The council of the college gratefully accepted the donation on the conditions in which it was offered and requested the treasurer to convey to the subscribers to the fund its sincere thanks for their gift. Part of the fund was expended in placing with Mr George Harcourt of London a commission to paint a portrait in oils of the late Dr Leech, also for presentation to the Owens College The artist has been successful in producing an excellent likeness and the portrait, which now hangs in the Christie Library has given general satisfaction. A large and artistic photograph of the portrait can be obtained at a cost of 4*s* by subscribers on making application to the honorary secretary of the fund Dr E M. Brockbank.

The Owens College

The address at the opening of the winter session at the Owens College will be delivered on Oct. 1st by Sir Dyce Duckworth.

July 29th

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS)

Small-pox

DURING the week ending July 26th there were notified four cases of small pox in Swansea. The tradesmen of the borough met on July 24th to consider the best means to remedy the evil that has been occasioned by the absurd and exaggerated reports of the health of Swansea. The meeting was a private one and the steps which it was decided to take have not been made known but the most useful would be to make public the fact that the inhabitants are protected by revaccination. To quote the words of Dr Wilfred W E Fletcher when he visited the town on behalf of the Local Government Board there are two kinds of scares—a scare which might do serious harm to a town is undesirable but a scare that might lead people to become so frightened of small pox that they would get revaccinated is very desirable.'

Health of Newport (Mon.).

In the annual report on the health of the county borough of Newport which has just been issued by Dr J Howard Jones the birth rate in 1901 is stated to have been 32 6 per 1000 the death rate from all causes 17 1 per 1000 and the infantile mortality rate 15 5 per 1000 births. More than 11 per cent of the deaths of infants were due to diarrhœa, a disease which of late years has been exceptionally prevalent and fatal in Newport, and in consequence of which Dr Howard-Jones has recommended the appointment of a female health visitor who should visit the homes of the poor and advice as to the feeding and care of young children Unfortunately this recommendation has not yet met with the approval of the corporation. It appears from information obtained that 75 female inspectors are already employed in 24 towns in England and Wales. During the five and a half years in which the Newport fever hospital has been in use 1207 cases of scarlet fever have occurred in the borough compared with 2280 notified during the five and a half years prior to the establishment of the hospital. In 1901 there were removed to the hospital 57 per cent. of the cases of scarlet fever 34 per cent. of those of diphtheria, and 85 per cent of those of typhoid fever The staff of three inspectors appears to be quite inadequate to the needs of a town with a population of 67 000 persons and it is not surprising to find that house-to house inspection has had to be almost entirely discontinued. In the 170 houses which were so inspected no fewer than 307 nuisances were discovered the necessity for the work is therefore apparent

Sanitary Inspectors Association

Although the Sanitary Inspectors Association of South Wales and Monmouthshire was only established in 1898 it has already accomplished a great deal of useful work. Three or four times a year the members of the association meet together in different parts of their district and discuss subjects connected with their special work They met last at Newcastle Emlyn in Carmarthenshire on July 25th and 26th, when Mr Joshua Powell, M.R.C S Eng, the medical officer of health for Llandyssul rural district gave an interesting address upon rural sanitation A paper by Mr D J Thomas, D P H, the medical officer of health of Merthyr Tydvil, was also read. Mr Thomas dealt more particularly with the difficulties attending the work of sanitary officials in Wales and especially in connexion with the precautionary measures necessary to prevent the spread of infectious disease owing to the doctrine of fatalism which was accepted by so many of the Welsh people. There is no doubt a great deal of truth in his contention, for there are few if any medical practitioners outside the large towns of the principality who when advising the separation of an infected patient from the rest of the household have not been met with the interrogation, "What is the use? if they are to have it they will have it." Ministers of religion, if they would, might do a great deal in the way of combating this doctrine and thus be of service in lessening the amount of disease in the country

A proposed Clearing House for Meat Inspection

In an omnibus Bill promoted by the Swansea Corporation which was before a committee of the House of Commons on July 23rd and 24th an important clause to facilitate the inspection of meat was rejected by the committee The clause provided for the establishment of a clearing-house in the town to which all meat sold in Swansea, whether slaughtered within the borough or without, should be brought for inspection Although there is a well appointed public abattoir in Swansea during the past few years several butchers have built slaughter-houses just outside the borough boundary, thus increasing the difficulties of inspection and it was these difficulties which it was sought to lessen by the operation of the rejected clause.

Heavy Fine upon a Milk Dealer

A Bristol milk dealer was convicted at the Cardiff police court on July 22nd for selling milk from which 35 per cent. of fat had been extracted. Three previous convictions under the Sale of Food and Drugs Act, 1875 having been proved, the prosecuting solicitor claimed that the convicting justice had no option but to inflict a fine of £100, for Section 17 of the Sale of Food and Drugs Act, 1899, enacts that "where under any provision of the Sale of Food and Drugs Act, 1875, a person guilty of an offence is liable to a fine which may extend to £20 as a maximum, he shall be liable for a second offence under the same provision to a fine not exceeding £50, and for any subsequent offence to a fine not exceeding £100" Although the stipendiary magistrate did not uphold this view he inflicted a fine of £90 or in default of payment three months' imprisonment.

Müller Orphan Houses Ashley Down, Bristol

The sixty-third annual report of this institution which has just been issued states that at the end of May, 1902, the total number of orphans was 1659, an increase of 224 as compared with the corresponding date of 1901 The financial statement shows that the expenditure amounted to £24,463 and that a favourable balance remains

Bristol Royal Infirmary

At a meeting of ladies held at the Bristol Royal Infirmary on July 25th, under the presidency of the Dowager Duchess of Beaufort, it was decided to form a "Royal Infirmary League" the object of which is to promote the interests of the Bristol Royal Infirmary and to endeavour, with the funds committee of that institution, to increase the income by £4000 per annum.

July 28th.

SCOTLAND

(FROM OUR OWN CORRESPONDENTS)

A Memorable Graduation Day at Edinburgh University

SATURDAY July 26th, was a memorable day for the annals of the Edinburgh University It was a brilliant inspiration that led the university authorities to offer their highest honour to the galaxy of distinguished men who received the LL.D degree on Saturday Six colonial Prime Ministers and four governers added to the tale of honorary alumni is probably a unique record for any university and whoever the inspired instigator may have been he deserves the gratitude both of the university and of the city The weather was a bad sample of an ungenial season in the morning when people had to find their way to the McEwan Hall it rained with a volume of water not common in our climate Notwithstanding that, the hall was promptly filled shortly after the doors were opened and it never presented a brighter and more impressive appearance The Vice Chancellor, Sir William Muir, presided, and he was supported by the university authorities and professors and by representatives of the two Royal Colleges and of the Town Council. The Dean of the Faculty of Divinity opened the proceedings with prayer Thereafter the Dean of the Faculty of Law, Sir Ludovic Grant, presented the following for the honorary degree of Doctor of Laws — General the Right Hon Lord Grenfell, G C B, G C M G, Governor and Commander in Chief Malta, the Right Hon. Sir Joseph West Ridgeway, G C M G, K.C B, K.C S.I, Governor of Ceylon, the Right Hon Sir Wilfrid Laurier, G C M G, Prime Minister of the Dominion of Canada, the Right Hon Sir Edmund Barton, K.C, G C M G, Prime Minister of the Commonwealth of Australia, the Right Hon. Richard John Seddon, Prime Minister of New Zealand, Lieutenant-Colonel the Right Hon Sir Albert Henry Hime, R.E, K.C M.G, Prime Minister of Natal, the Right Hon Sir Robert Bond, K.C M G, Prime Minister of Newfound land, Sir Walter Joseph Sendall, G C M G, lately Governor of British Guiana, Sir William McGregor, M D, K.C M G, C B, Governor of Lagos, and the Right Hon Sir John Gordon Sprigg, K.C M G, Prime Minister of Cape Colony (*in absentiâ*) Sir Ludovic Grant is a master of the particular art required for such a ceremonial and he never acquitted himself more admirably than on this occasion Each one of this distinguished group of men as he was presented received a flattering ovation from the crowded hall After signing the roll book of honorary graduates each was led to a chair in front of the platform where he was face to face with the occupants of the hall and was in a position to see the stately proportions and rich adornment of the hall to great advantage The ceremonial and the spectacle could not fail to make an indelible impression upon the men who guide the empire across the seas, and no one present in the hall is likely to forget it. While the granting of the honorary degrees was of exceptional interest on this particular occasion, the occasion was also the main one for the conferring of medical degrees. The number of men taking the doctorate in medicine was unprecedentedly large, there being 67, while 150 students took the Bachelor degree Five gold medals were awarded for theses, and of the five students who graduated with first-class honours two were women. After the graduation ceremonial the colonial premiers and governors were entertained to luncheon at the Students' Union In the afternoon the premiers had the freedom of the city conferred upon them and in the evening they were entertained at a banquet. At the close of the graduation ceremonial in the morning Professor E A. Schäfer, F R.S, addressed the graduates, dealing with the advantages of the medical profession, the changes in medical problems within recent years, and the altered methods of attacking disease He then proceeded to point out the need that Edinburgh had for a chair of chemical physiology the holder of the chair to be a chemist in the first place.

The Allocation of the Carnegie Trust Money

The Carnegie trustees have published a letter which they have sent to the secretaries of the University Courts of the four Scottish universities dealing with the allotment of the money at their disposal for the four universities. The letter embodying the plan adopted by the trustees is too long to deal with in detail here but it may be said that the general plan is characterised by great ability and a statesmanlike grasp and treatment of a problem which to many minds appeared extremely intricate The trustees retain complete control of the £50 000 per annum, which is the sum available The sums allocated to the universities are as follows Glasgow gets for five years £8000 for buildings and permanent equipment, £2000 for teaching but £1500 of this are annually set aside for an endowment fund for a specified chair, and £1000 for the library This makes a total grant of £11,000 per annum and so of £55 000 in five years Aberdeen gets £45,000 on the same lines St Andrews £42 000, and Edinburgh £57,500 As regards Edinburgh, £8000 a year are allowed for buildings and permanent equipment, and under this head are included (1) natural philosophy and engineering (2) strong room and alterations in library (3) apparatus (4) pathological bacteriology and (5) catalogue of anatomical museum, £2500 a year are given for teaching and it is indicated that this sum is for the endowment of modern languages or some other purpose approved by the committee, and £1000 are allocated annually to the library By the allotment of £2500 per annum for teaching on the lines indicated by the trustees a professorship or lectureship can be at once instituted with £500 a year for its maintenance for five years, while at the end of that period there will be an endowment of £10 000 with accumulations of interest. At the end of the period of five years the trustees keep themselves free to rearrange the allotment of their funds as they think fit. The above disposes of £200 000 in five years which leaves £10 000 still in the hands of the trustees and they indicate that this sum will to a considerable extent be devoted to the aid of post graduate research and to the foundation of scholarships designed to stimulate original work in special directions It is needless to dwell upon the enormous boon that these arrangements afford to the Scottish universities I have no means of knowing if the universities like being supervised in this way by an outside body even though they be Carnegie trustees but so far as I have been able to gather the scheme has appealed to persons outside the university for its breadth and powers, and it may be that the university authorities are thankful to have such an outside tribunal to determine which amongst conflicting claims is the most urgent. The trustees are certainly to be congratulated on the remarkable skill shown in this scheme

Royal University of Ireland

THE Senate of the Royal University met on July 24th when a motion expressive of sympathy and congratulation was unanimously adopted and forwarded to His Majesty the King The following were appointed as extra examiners for the autumn examinations 1902 —In surgery Mr Charles Stonham C M.G in midwifery Dr Henry Jellett, in pathology Dr Ale ander C. O Sullivan and in ophthalmology Dr William G Sym On the motion of Dr Cox seconded by Dr W A. McKeown Sir Christopher Nixon was unanimously reappointed representative of the University on the General Medical Council for the ensuing five years

Royal College of Surgeons in Ireland

The following prizes were awarded for the Summer Session, 1902 —Barker anatomical prize (£30) R. G Allen Carmichael scholarship (£15) J J Connolly Silver medals in operative surgery W R Ormsby and J J Ryan (equal) Practical histology W W Boyce first prize (cheque) and medal and A. C. Adams, second prize (cheque) and certificate. Practical chemistry C M Burton first prize (cheque) and medal and J B Kelly second prize (cheque) and certificate. Public health and forensic medicine F O D Fawcett, first prize (cheque) and medal and L F Kelly second prize (cheque) and certificate. Materia medica P V Dolan, first prize (cheque) and medal and H. S Mistear second prize (cheque) and certificate. Practical pharmacy C M. Burton first prize (cheque) and medal and R. J Smallman second prize (cheque) and certificate. Biology C M Burton first prize (cheque) and medal and A. J Faulkiner second prize (cheque) and certificate. The schools of surgery will resume work after the summer recess on Oct. 1st.

Typhus Fever in Ireland

An epidemic of typhus fever prevails at present at Clifden on the west coast of Galway Trained nurses were summoned from Dublin and of those sent down from the Mater Misericordiæ Hospital two were attacked by the disease One of them Miss Tyrrell was invalided and sent back only however to die as the result of the conscientious discharge of her dangerous duties The other nurse who was infected is now happily convalescent It is interesting to note that there is at present no typhus fever along that part of the west coast which includes Burton Port and the Arran Islands Mr Henry E. Earnley L.R.C P & S Irel, came from Manchester some months ago to undertake the position of local medical officer in succession to the late Mr William Smyth and is there now doing courageously the work which proved fatal to the heroic Mr Smyth whose name is familiar to all readers of THE LANCET He reports that there is no fever there at present, and that it does not usually appear until later in the year when the harvesters come from Scotland He remarks that a sick call to one of the islands generally means two hours on the sea. He does not, however complain but seems rather to prefer his life in that wild and desolate region with all its dangers from typhus fever shipwreck, and exposure to the daily drudgery of a general practitioner working in the streets of a great city

The Centenary of Bichat

THE Centenary of Bichat was celebrated on July 22nd, under the auspices of the French Society of the History of Medicine. The programme gone through was as follows At 10 A M the members paid a visit to the tomb of Bichat in Père Lachaise where Professor Blanchard delivered an address. At 4 P M a meeting was held at 14 Rue de la Chanoinesse, the house where Bichat lived and died and to which a commemorative plaque has been fixed At 5 P M a meeting was held at the Faculty of Medicine where Professor Tillaux gave an address and Dr Albert Prieur delivered an eulogium of Bichat. Finally a marble plaque was affixed to the walls of the Hôtel Dieu on which was inscribed the text of the testimony to the memory of Bichat which Bonaparte wrote with his own hand A medal bearing the effigy of Bichat has been struck in memory of the centenary and every subscriber has received one. Two descendants of Bichat are alive at the present day—namely a grandson and a great niece.

Assassination of a Medical Man.

A Paris physician Dr Ordenstein a German by birth has just been mysteriously assassinated. He was travelling in a first-class carriage to Versailles and when close to Becon les-Bruyères he was stabbed several times with a knife by a young man employed in the Post Office, by name Chalmnoix who refused any explanation of his conduct but said that he had been poisoned Dr Ordenstein was taken to the Beaujon Hospital in a dying condition and he expired on the following day He had a severe abdominal wound Dr Ordenstein was about 60 years of age He had lived in Paris for more than 20 years and was a bachelor His medical studies had been carried on in Paris and he wrote his thesis on paralysis agitans and disseminated sclerosis the materials for which had been collected at the Salpêtrière under Charcot.

The Chair of Anatomy at the Faculty of Medicine

The Council of the Faculty of Medicine devoted the whole of its last meeting to the question of the chair of Anatomy A proposal was made that the professor of anatomy should be precluded from also holding an appointment as hospital surgeon in which case the duties of demonstrator (*chef des travaux anatomiques*) and professor could have been combined in the same individual who would thereby have had an income of about £1000 a year This proposal however was rejected and it was decided (1) that no additional conditions should be imposed on the professor of anatomy and (2) that the demonstrator should not in future be chosen by competition but should be nominated by the council of the Faculty who would select him from among the *agrégés* When the period of service of Dr Rieffel the present demonstrator expires by lapse of time the appointment of demonstrator will be annual and renewable. One result of this will be that the professor of anatomy will be supreme in that department whereas previously the demonstrator had undivided authority at the École Pratique

The Competitions for the Post of Hospital Physician.

Mention has recently been made in these columns[1] of the scandals which have arisen in connexion with the competitions for nomination as hospital physician or surgeon The meet together in different parts of their district and discuss subjects connected with their special work They met last at Newcastle Emlyn in Carmarthenshire on July 25th and 26th, when Mr Joshua Powell, M.R.C S Eng , the medical officer of health for Llandyssul rural district gave an interesting address upon rural sanitation. A paper by Mr D J Thomas, D P H , the medical officer of health of Merthyr Tydvil, was also read. Mr Thomas dealt more particularly with the difficulties attending the work of sanitary officials in Wales and especially in connexion with the precautionary measures necessary to prevent the spread of infectious disease owing to the doctrine of fatalism which was accepted by so many of the Welsh people There is no doubt a great deal of truth in his contention, for there are few if any medical practitioners outside the large towns of the principality who when advising the separation of an infected patient from the rest of the household have not been met with the interrogation, "What is the use ? if they are to have it they will have it." Ministers of religion, if they would, might do a great deal in the way of combating this doctrine and thus be of service in lessening the amount of disease in the country

A proposed Clearing House for Meat Inspection.

In an omnibus Bill promoted by the Swansea Corporation which was before a committee of the House of Commons on July 23rd and 24th an important clause to facilitate the inspection of meat was rejected by the committee The clause provided for the establishment of a clearing house in the town to which all meat sold in Swansea, whether slaughtered within the borough or without, should be brought for inspection Although there is a well appointed public abattoir in Swansea during the past few years several butchers have built slaughter houses just outside the borough boundary, thus increasing the difficulties of inspection and it was these difficulties which it was sought to lessen by the operation of the rejected clause

Heavy Fine upon a Milk Dealer

A Bristol milk dealer was convicted at the Cardiff police court on July 22nd for selling milk from which 35 per cent. of fat had been extracted. Three previous convictions under the Sale of Food and Drugs Act, 1875 having been proved, the prosecuting solicitor claimed that the convicting justice had no option but to inflict a fine of £100, for Section 17 of the Sale of Food and Drugs Act, 1899, enacts that "where under any provision of the Sale of Food and Drugs Act, 1875, a person guilty of an offence is liable to a fine which may extend to £20 as a maximum, he shall be liable for a second offence under the same provision to a fine not exceeding £50, and for any subsequent offence to a fine not exceeding £100' Although the stipendiary magistrate did not uphold this view he inflicted a fine of £90 or in default of payment three months' imprisonment.

Müller Orphan Houses Ashley Down, Bristol

The sixty third annual report of this institution which has just been issued states that at the end of May, 1902, the total number of orphans was 1659, an increase of 224 as compared with the corresponding date of 1901. The financial statement shows that the expenditure amounted to £24,463 and that a favourable balance remains

Bristol Royal Infirmary

At a meeting of ladies held at the Bristol Royal Infirmary on July 25th, under the presidency of the Dowager Duchess of Beaufort, it was decided to form a "Royal Infirmary League,' the object of which is to promote the interests of the Bristol Royal Infirmary and to endeavour, with the funds committee of that institution, to increase the income by £4000 per annum

The Competitions for the Post of Hospital Physician

Mention has recently been made in these columns[1] of the scandals which have arisen in connexion with the competitions for nomination as hospital physician or surgeon The commission appointed by the Hospitals Medical Society to consider the modifications required in these competitions, conformably with the resolutions agreed to at the meeting held on June 18th, has now presented its preliminary recommendations The chief objects which the commission had in view were to guarantee that the competitions would be impartial, to reduce their inordinate length, and to lighten the task both of the candidates and of the examiners. Some of the questions proposed for its consideration appeared to present so many difficulties that the commission preferred to reserve its opinion until further experience should have been gained The commission recommends in the first place that the examinations for nomination as hospital physician or surgeon should be divided into two competitions—namely, a preliminary stage (*concours d'admissibilite*) and a final stage (*concours d'admission*) It is further recommended that the present method of voting should be abandoned and that the jury should give its votes at the end of each sitting and after discussion of the results of the examinations and that the decisions should be made known as soon as they are arrived at. The *concours d admissibilité* would be decided by a jury of 10 It would commence with a written examination in pathological anatomy and in symptomatology or semeiology, these two subjects being dealt with quite separately, each as a paper by itself For the reading of these two papers the jury would be divided into two sections of five each, determined by drawing lots, one section to decide as regards pathological anatomy and the other as regards symptomatology The maximum number of marks of each subject would be 15 After this first examination the number of candidates would be reduced to 30 at most, who would then proceed to the clinical examination of a patient, 15 minutes being allowed for the actual examination, five minutes for consideration, and 15 minutes for the candidates to state their opinions orally to the jury The maximum number of marks here would be 20 After this second examination the number of candidates would be reduced to 20, who would then proceed to deliver a discourse (*leçon orale*) on a question in pathology, either internal or general, 20 minutes being allowed for preliminary consideration of the discourse and the same length of time for its delivery The maximum number of marks here would be 20 This examination, as well as the previous one, would be adjudicated on by the whole of the jury After this examination 12 candidates would be declared "admissible" The final competition will be the *concours d'admission* As only three candidates can be placed by a competition, there will be two competitions for the nomination of six hospital physicians or surgeons. A jury of nine members will be formed, none of whom must have either taken part in the *concours d'admissibilité* or drawn lots rendering them eligible to take part in it The *concours d'admission* will consist of two parts (1) a written opinion on a case, a quarter of an hour being allowed for the examination of the patient and three-quarters of an hour for the writing of the opinion, with a maximum of 20 marks attainable, and (2) a clinical lecture on a patient, half an hour being allowed for the examination of the patient and the consideration of the case the interview with the patient not to exceed 20 minutes, and a maximum of 30 marks being attainable.

July 29th

NEW YORK

(FROM OUR OWN CORRESPONDENT)

Transportation of Mosquitoes by Vessels

DR. SOUCHON, President of the Louisiana State Board of Health, in view of the fact that the presence or absence of mosquitoes on board of vessels may be considered as a basis for quarantine regulations, caused observations to be made by the marine medical inspectors whom the board of health of that State places aboard of vessels coming from the fruit ports of Central America carrying passengers or trading with infected ports or with such as are specially dangerous Six of the inspectors found no mosquitoes aboard but two of these considered that rough weather was the probable cause of the absence of the insect. Four inspectors reported mosquitoes throughout the entire voyage from Limon, occupying five and a half days. The final inspection ha to be made just before the vessel enters the Mississippi river quarantine station, for mosquitoes always invade ships at this point.

Uniform of the Medical Department of the United States Army

According to the *New York Medical Record* a change is shortly to be made with regard to the insignia of the United States Army Medical Department and hospital corps Instead of a cross a caduceus is to be worn The board of officers which is now engaged in revising the uniform of the army also proposes to change the distinctive colour of the medical department from green to magenta. This is in conformance with the custom of most countries, for dark red, magenta, or maroon is the distinctive colour not only of the medical department of the United States navy but also of those of 13 of the most important armies of the world, including those of England, France, Germany, Austria, and Russia.

Army Nurses

The army corps of nurses was established by a Bill passed by Congress in February, 1901, and the War Department has issued orders relative to the duties, pay, status, and quarters of the corps Army nurses are to be assigned to duty at military hospitals, and at hospitals where more than one nurse is serving one of the nurses will be assigned to duty as chief The tour of duty outside the United States will generally be at least two years Nurses are appointed for three years and must be graduates of a hospital training school and pass satisfactory professional, moral, mental, and physical examinations Application for service is made to the surgeon general, and after appointment the nurse is expected to serve at least three months in the United States, during which term she will receive special instruction in army nursing A nurse who has served faithfully and satisfactorily for at least six months and received an honourable discharge will be placed on the reserve list. A nurse will be dropped from the reserve list upon reaching the age of 45 years, or if she ceases for five years to practise her profession, or if she becomes permanently incapacitated owing to illness or other good or sufficient reasons

Immigration and Disease

Immigration to the United States at the present time presents many serious problems The type of immigrant has completely changed within the past 30 years and the incoming passenger steamers are crowded now with the inhabitants of Southern Europe, of the Orient, and of Russia. A great number of these people are undesirable in many ways, not the least so from the standpoint of health. According to Mr T V Powderley, Commissioner General of Immigration, persons afflicted with favus and trachoma are numerous To prevent the incoming of such individuals regulations, of which the following forms part, were framed by Mr Powderley and approved by the Secretary of State "In view of the prevalence among arriving immigrants of favus, a loathsome contagious disease, you are hereby instructed to make a careful examination in order to insure the detection of all such cases and their immediate return to the country whence they came, if possible by the steamship upon which they arrive, otherwise as soon as practicable by a steamship of the same line at the expense of said line If the certificate of the examining physician in this country indicates that the disease existed at the time of alien's embarkation, or that symptoms had developed at that time which the transportation company's physician might with reasonable care have detected, steps should be taken for the prosecution of such company, as provided by Section 6 of the Act of March 3rd, 1891"

Contagious Disease Hospitals in New York City

The conditions of the hospital accommodation in New York city for those suffering from contagious diseases are notoriously bad and have been made recently the object of much vituperation on the part of the lay press The first step in the direction of improvement was made a short time ago when a sum of $37,000 (£7400) was set aside by the board of estimate and apportionment for the specified purpose ' of the care and maintenance of patients suffering from contagious diseases" Of course such an amount as the above is miserably inadequate and will be employed to patch up the old buildings which are used as small pox hospitals on North Brother Island. There is pressing need in New York of better isolation hospitals for contagious cases

July 19th.

THE BRITISH MEDICAL ASSOCIATION

MEETING AT MANCHESTER.

THE meeting of the British Medical Association at Manchester this year marks its seventieth anniversary and it is the fourth occasion on which the Association has assembled in that city Its first meeting was as long ago as 1835 before the Association was known by its present name the second was in 1854, the third in 1877 when slightly under 1000 members were present

The critics who not infrequently assert that the annual meetings of the Association have lost their scientific value and have developed into gatherings of the picnic order will this year at least acquit the executive of choosing a meeting place the attractions of which are calculated to draw members away from the serious business of the occasion for a more unlovely place than Manchester for anything of a picnic character it would be difficult to choose.

Tradition has it that it always rains in Cottonopolis certainly it is always dirty and tradition is not belying the character of the city on the present occasion, as the weather is very unsettled and showers of rain are frequent. The noise occasioned by street traffic in Manchester is continuous and distressing There is no such thing as smooth roadways in the city no asphalte or wood blocks, while rubber tyred vehicles are an exception. Moreover the setts are badly laid, quite big gaps occurring here and there. The consequence is a continuous clatter which defies description and creates considerable distraction and confusion At no time is this infliction on the ear to any extent abated. It is as the noise of a car rattling o'er the stony street,' in Byron's Waterloo only multiplied ten thousand times.

On Monday evening Mr Walter Whitehead entertained at dinner the presidents of sections, local secretaries, the members of the council, vice-presidents and various other guests Among the latter were the Dean of Manchester the Rev Mr Brown of the Roman Catholic Church of the Holy Name the Lord Mayor of Manchester the Mayor of Salford the Hon. G Rockwood, member of council (Colombo) and Dr H P Cholmeley (representing THE LANCET) The dinner was held at the Albion Hotel. Dr Rockwood who is a pure Tamil graduated in medicine in Madras in 1872 and 12 years later became M R.C S. Eng M.R.C P Lond He is consulting surgeon to the General Hospital at Colombo, with which institution he has been connected for a quarter of a century and was appointed in 1898 to be an unofficial member of the Legislative Council of Ceylon. The toasts were The King and the Queen " proposed by Mr Walter Whitehead (President elect) The President-elect, by the Lord Mayor of Manchester The Lord Mayor of Manchester by the President-elect and The Mayor of Salford by the Dean of Manchester

A striking work commemorative of the meeting of 1902 has been written by Dr William Stirling and produced at the joint expense of himself and Mr Whitehead. The work has been privately printed and issued at the Owens College Laboratory of Histology It is entitled Some Apostles of Physiology" and consists of short biographical notices of leaders in physiology from Vesalius to Huxley The work is most sumptuously illustrated with reproductions of cuts from the works of the various masters in physiology and with photogravure reproductions of portraits of themselves We hope in a future issue to give an extended review of this book, which is worthy in every way of the great men commemorated therein, of the distinguished physiologist who has written it, and of the able surgeon with whose presidency of the British Medical Association its issue coincides

As at Edinburgh and at Cheltenham all the sections this year are housed under one roof—namely in the Owens College The reception room and the various executive offices are also in the same group of buildings. The advantages of this arrangement are obvious, but of course, only towns having a large educational establishment possess the necessary accommodation for thus housing a scientific meeting

The annual service in the Cathedral on Tuesday morning suffered in point of attendance in consequence of a heavy fall of rain just prior to the time appointed for the commencement of the service. The musical portion of the Office was well rendered by the Cathedral choir and Bishop Thornton, vicar of Blackburn preached an eloquent sermon on the text, Neither shall there be any more pain for the former things are passed away " (Rev xxi. 4). The alms were, as usual, divided between Epsom College and the British Medical Benevolent Fund. There was also a service for Roman Catholic members of the Association at the Church of the Holy Name, High Mass being celebrated by the Rev Mr Brown and a sermon preached by the Rev Mr Coupe, S J

The annual exhibit of drugs surgical and sanitary appliances, and special foods was held in the drill hall in Burlington-street, a somewhat squalid neighbourhood within five minutes walk of the Owens College. Most of the stalls were ready for the opening ceremony which was held on Monday evening at 7 30 the Lord Mayor of Manchester declaring the exhibit open in a few brief sentences having first been introduced by Dr S. Woodcock the chairman of the Exhibits Sub-committee A programme of music was provided by the Euterpean Orchestra.

The exhibits were thoroughly representative of all that pertains to the healing art, features this year being a sanitary section and a motor car section As special space was allotted to this class of exhibit ample room remained for pharmacological exhibits, sanitary appliances, and special foods. The drill hall did not, however afford the same facility for making the general presentation of the stalls artistic as did the Winter Garden at Cheltenham last year Like most drill halls the building is strictly rectangular and the passages between the stalls served to cut the space into squares Nevertheless the stalls for the most part were attractively arranged and very general interest was taken in the exhibits by the visitors and the attendance was good despite the wet weather and the remoteness of the drill hall from the neighbourhood of the leading hotels

The buildings in Manchester give striking evidences on all sides of the continuous bombardment of the smoke-laden air Columns of brick and stone seem as though they had been held in a smoky flame. The sooty deposit appears to be quite thick in places. Where so much steam power is in request as in an extremely busy manufacturing centre like Manchester this befoulment by smoke is looked upon as inevitable. But why cannot Manchester prevent smoke as Nottingham has done? Perhaps however cotton goods are not so easily spoilt by smoke as is lace otherwise it may reasonably be supposed that the manufacturers in Manchester would soon find a remedy

As is well known Manchester has attacked many sanitary problems courageously and with success notably the supply of pure water to the city and the disposal of sewage Is the smoke question less in importance than these? It is doubtful.

The water supply is derived from Lake Thirlmere in Cumberland, and is, of course, remarkably soft—a fact readily noticed by the visitor who is accustomed to hard water On account of immense industrial waste the sewage problem in Manchester has been very difficult to deal with At a quite recent meeting, however, of the Mersey and Irwell Joint Committee it was reported that where land was available perfectly trustworthy results with tanks and filters were obtained so long as the land, tanks, and filters were not overdosed and their bacterial purifying agencies choked Special steps are also taken to utilise refuse other than sewage with decidedly satisfactory results

The first general meeting was held on Tuesday afternoon at 2 P M in the Whitworth Hall, Owens College, and was adjourned until the evening when Mr Whitehead delivered the interesting presidential address which will be found in our columns.

The address in Medicine, which we also publish this week, was delivered to the assembled Association in the Whitworth Hall by Sir Thomas Barlow on Wednesday evening Previously to the delivery of the address the President read a telegram from His Majesty the King expressing his thanks for the message of congratulation which had been sent by the Association on the preceding day

At this meeting Mr Andrew Clark, treasurer of the Association, stated that the meeting of 1903 would be held at Swansea and that Dr T D Griffiths would be the President Dr Griffiths expressed his thanks and then Dr Roberts Thomson, chairman of the Council of the Association, announced that the council had accepted with great regret the resignation of Mr Francis Fowke, the general secretary, who was unanimously elected an honorary member of the Association.

The news of the resignation of Mr Francis Fowke, the general secretary of the Association for the past 31 years, will be received by all members of the medical profession with feelings of concern Mr Fowke's period of office covers stormy times in the history of the Association, for which he has zealously laboured, and he will convey with him on his retirement the hearty good wishes of his very many friends For ourselves, we congratulate him on his well earned rest and assure him of our sympathy in the severance of ties of so long standing We also take the opportunity of thanking him for the courtesy invariably extended by him to our representatives on so many occasions

Mr George Brown, one of the Direct Representatives for England and Wales on the General Medical Council, desires us to state that the death of a near relative prevented him from taking part in the discussions in the Ethical Section of the Manchester meeting of the British Medical Association.

THE GENERAL MEETINGS

THE FIRST GENERAL MEETING

The First General Meeting of the Association was held in the Whitworth Hall, Owens College, at 2 P M, on July 29th There was a fair attendance of members.

The minutes of the last annual meeting were, on the ion of Dr G B **FERGUSON**, the retiring President, con ed and adopted. Dr Ferguson then, after a short well speech, vacated the chair in favour of his successor, Mr Walter Whitehead, F R C S Edin, consulting surgeon to the Manchester Royal Infirmary

Mr **WHITEHEAD**, after thanking the Association for electing him, gave notice that he would move that a telegram should be sent to His Majesty King Edward VII congratulating him on his recovery This motion being duly adopted the Presidential badge was presented to Mr Whitehead by Mr J W Smith on behalf of the Executive Committee

Dr R **THOMSON** then proposed, and Dr **HENRY BARNES** seconded, a vote of thanks to the retiring President. This was carried unanimously and Dr **FERGUSON** then replied in a few well chosen words

The **TREASURER** (Mr Andrew Clark) then proposed —

> That the financial statement for the year ending Dec. 31st 1901, together with the estimate for revenue and expenditure for 1903, be received and adopted

This was duly seconded and then Dr J **BRASSEY BRIERLEY** spoke a few words of warning He contended that the estimated increase due to an increased subscription—namely, £7200—would not be attained because many subscriptions would be dropped. Mr **ANDREW CLARK** replied and the motion was carried.

The next business was the vote of thanks to Mr Andrew Clark whose term of office had come to an end. This was carried unanimously The auditors, Messrs Price, Waterhouse, and Co, were then appointed in accordance with the statute and the meeting passed to the election of a new treasurer

Mr **GEORGE EASTES** proposed for this office Dr Edward Markham Skerritt of Clifton

This was seconded by Mr **JOSEPH COLLIER**, and on the motion being put to the meeting Dr Skerritt was unanimously elected.

The meeting then adjourned.

THE (ADJOURNED) FIRST GENERAL MEETING

The adjourned first general meeting assembled in Whitworth Hall at 8 30 P M, and was reinforced by a large number of ladies who came to assist at the conversazione which was to follow Indeed, the great hall was quite filled and the academic robes rivalled in their startling scarlet the brilliancy of the ladies' evening dresses After an organ *recital by Dr Kendrick Pyne, organist of the Cathedral*, the **LORD MAYOR** opened the proceedings with a few appropriate words of welcome He insisted that the people of Manchester fully recognised how much they owed to the medical profession and moved a vote of thanks to those who had come from all parts and some from great distances to take part in the proceedings This proposal was carried by acclamation Mr W Coates, honorary secretary to the Executive Committee, then introduced the colonial visitors and delegates. He read out a long list of names, and those who were present responded to their names by mounting the platform where they were received each with a round of applause. The first name was that of Professor Baginsky (Berlin), then followed Professor von Noorden (Frankfurt), Professor Musser (Baltimore), Dr Jules Comby (Paris), Professor Onodi (Budapest), Dr Widmark (Stockholm), Professor Oscar Liebreich (Berlin), Dr L Grünwald (Munich), Dr T Röhrer (Zürich), Professor G Killian (Freiburg-in-Baden), Dr the Hon W G Rockwood (Ceylon), Dr J Hyslop, D S O (Pietermaritzburg), Mr H. H McWilliams (West Australia), Mr James Grant (Ottowa), and others.

Mr **WALTER WHITEHEAD** then delivered his Presidential Address, which we publish in full on p 261.

At the conclusion of the address a vote of thanks to the President was moved by Mr **THOMAS BRYANT** and carried by acclamation.

As the sections broke up early on Wednesday afternoon members were surprised to find a notice posted up stating that the general meetings announced for Wednesday, Thursday and Friday would not take place. The reason given was that all the business had been concluded. This, however, only removes the question a stage further back, for it is natural to inquire why there was so little business The explanation will be found in the new constitution which is now in force and which stipulates that the meeting of delegates must precede the general meetings. It was, however, impossible to organise the election of delegates in time for the present annual meeting, so there had been *no* delegate meeting to prepare questions for the general meeting to decide, and hence according to the new rules there could be no further business to transact

THE SECTIONS

MEDICINE.

WEDNESDAY JULY 30TH

Dilatation of the Stomach.

Professor CLIFFORD ALLBUTT (Cambridge) opened a discussion on the *Causes* Diagnosis, and *Principles of* Treatment of Dilatation of the Stomach He commenced by offering on behalf of the section a tribute to the memory of *Professor Kussmaul, who died full of years* and honours on May 28th 1902, and to whose clinical studies from 1865 onwards on dilatation of the stomach he himself and the *profession* at large *were deeply indebted.* In entering upon the subject of the day he proposed that the discussion should run chiefly upon the atonic or non obstructive dilatations of the stomach, as the *obstructive* dilatations were, comparatively speaking well understood. Atony and atonic dilatation had not received the attention they deserved, atonic dilatation, *indeed, being neglected* by some physicians and by a few even denied. Dealing with the *causes* he was disposed to attribute acute dilatation of the stomach to *compression of* the *gut by* the distended viscus itself about the junction of the duodenum and jejunum. ‘ The stomach," he said, is supported more firmly at the *cardiac* than at *the pyloric end* , and in any case its mean position is more vertical than is generally supposed, especially when empty In estimating atonic dilatation, especially in its *lesser degrees* the area of the cardiac moiety is therefore to be carefully observed The stomach may drop as a whole into the mid-abdomen or hypogastrium and this *independently of more general* enteroptosis. Gastroptosis is not necessarily attended with dilatation. In this case the stomach assumes a wallet shape, the cardiac and pyloric orifices *approaching each other* or if the pyloric end slip more than the cardiac the position of the organ is more vertical and to the left. In this latter case the more muscular pyloric moiety *is apt to become dilated* by the gravitation of retained contents. The relation of gastritis to dilatation of the stomach is little understood. It would seem that excess of hydrochloric acid *is not necessarily* or perhaps usually in its earlier stages a consequence of gastritis it may rather be the cause of it. During life the presence or extent of gastritis is often assumed on *very slender* grounds and even our post-mortem knowledge of it leaves much to be desired. Relaxation of the stomach due primarily to muscular failure, and therefore appearing first in the pouch and fundus, may depend upon toxic causes or mere atony Such gastric distension, advancing to dilatation, not uncommonly retards convalescence from such diseases as typhoid fever and rheumatic fever When the condition follows slow digestion with fermentation anæmia, or mere inanition the muscular failure is primary That spasm of the pylorus may cause dilatation of the stomach, as, for example, in ulcer hyperchlorhydria or lumpy contents of the stomach, seems not improbable. Such morbid action is consistent with what we know of other sphincters but atonic dilatations rarely seem big enough to be due to a permanent spasmodic contraction of the pylorus, nor is the muscular coat, as we should expect, hypertrophied. In atonic dilatation peristalsis does not become visible That the nervous system may be concerned in paresis of the stomach seems likely enough from cases which have been observed. Not only may continuously depressing causes act in this way but sudden and grave mental shock may be quickly followed by considerable atonic dilatation of the organ. Alcohol may act directly as a poison to the muscular fibre or indirectly by extension of inflammation outwards, and thus be a cause of dilatation. Atonic dilatation of the stomach is no rare consequence of exhaustion by excessive *athletic* exertion *or* mental stress, especially in young people of delicate constitution Dilatation of the stomach is far from being rare in little children and infants in *whom it often comes on acutely* , but if the condition be understood it is readily relieved by an emetic or the tube The *symptoms* of atonic dilatation, to an observer not forewarned, are often indefinite if not *misleading* There may be little or no loss of appetite or dyspepsia in an early stage of the disorder food often relieves a sense of sinking Vertigo sleeplessness heaviness lassitude and fatigue and mental depression may divert attention to the nervous *system. Flatulence, indeed, is rarely absent, but the* tongue may be clean, vomiting slight or absent, the bowels constipated or the stools occasionally lienteric. The *heart is apt to flutter or to intermit and the abdominal* aorta to throb. In extremer cases the pulse falls in volume and pressure the hands become chilly the nails *livid and the face thin drawn, and sallow* By physical signs we may determine the size and position of the stomach. In thin persons gastroptosis is not difficult to *ascertain (in well nourished persons it never seems to occur)* and it is for the most part curable by rest, massage and better nutrition. When as is usual the dilated stomach *occupies (approximately) its normal position detection of the* disorder by physical signs will generally speaking be easy Under ordinary circumstances peristalsis is never visible as *in obstructive dilatation and the signs of distension are* chiefly notable to the left of the middle line and under the lower ribs the ballooned stomach is apt to push up the *diaphragm and to encroach upon the thorax.* The area of resonance may rise to the fifth or fourth rib and may extend to the posterior axillary line. Such a stomach often accompanies *diseases of the heart and plays a large part in the* patient's distress Physical examination must be made at various periods of digestion and when the stomach ought to be empty *In health the stomach after a meal should contract* upon its contents, when an area of dulness rather than of resonance will become apparent. Even in acute indigestion *there is a considerable grip of these contents*, a grip often attended with stomach ache, but in atony with or without static dilatation an area of resonance at the cardiac end will be *found almost immediately after a meal* even four or five hours after a meal the vault remains high and, behaving capriciously under gaseous influences, at no *time does it contract in any regular periods. Thus the* pyloric moiety, in its turn unable to withstand the gravitation of its contents increases from its comparatively small trans*verse diameter until the stomach as a whole may assume a* uniform thick sausage shape, the upper outline of which may include the nipple and the lower the navel. Strangulation *by sharp flexure of the pyloro-duodenal portion may occur in* particular cases but such cases are not so common as we suppose. Dropped kidney is often rather in association with *atonic dilatation or gastroptosis than a cause of them* though Sir William Bennett and Mr Bidwell have incidentally relieved dilatation by fixation of a right kidney *Dilated colon may be mistaken for a dilated stomach and in* rare cases the error may be unavoidable but in the vast majority of instances by discriminating percussion even without intubation these two organs may be distinguished. The stomach may no doubt be wholly concealed by the colon, but ordinarily some narrow area of stomach resonance can be obtained, when a difference of percussion note either in pitch or clang can be made out. In difficult cases syphonage or insufflation may help us Von Ziemssen recommended in such cases alternate inflation of colon and stomach. The tuning fork auscultо-percussion and coin tapping in my experience, add little or nothing to what careful percussion can reveal. In a healthy stomach no "squelchy" sounds should be obtainable they are usually obtainable in atonic dilatation but rarely amount to the succussion splash of obstructive dilatation. If before breakfast squelching can be obtained after the drinking of a tumbler or two of water we have to deal with a flabby and extended stomach. The use of the tube is of cardinal importance for diagnosis if not for treatment, but among private patients in England this method is resented and makes but little way The normal fasting stomach contains at least from 20 to 30 cubic centimetres of residual fluid and may hold even 100 but quantities above 100 cubic centimetres are morbid. In the normal state this residuum should not contain any particles recognisable as remnants of food seeds, grit, or fibre in vomit or stool should be carefully noted and the date when they were swallowed ascertained The larger the residuum and the more obvious the relics of food the worse the case A considerable admixture of mucus may indicate the presence of gastritis In atonic dilatation sarcinæ and torulæ are not usually found lactic acid but rarely and in small quantity The quantity of water accepted by the stomach gives us little information individual *tolerance is very variable but in atonic dilatation the* return of it is very feeble, or perhaps is obtained only by expression or syphonage. Illumination of the stomach from *within is of* little service. From radiography we may hope for some more information Chemical tests for the delay of ingesta, such as salol or potassium iodide, may corroborate but cannot dictate a diagnosis The *treatment* of atonic dilatation must largely depend upon the causation of the individual cases, particular symptoms will often indicate the means of their own palliation Vertigo often very severe, and lassitude after meals often depend upon distension of the stomach and may be quickly relieved by careful regulation of diet and restriction of fluid at meals to the lowest quantity In sleepless cases, besides these measures, hydrotherapy expertly carried out is often the more useful as it takes the patient away from work and care into a bracing climate In heart disease, after much disappointment in the use of specific remedies, the cure or relief of an atonic dilatation of the stomach may be attended with remarkably good effects. Such patients, under the guise of a light diet, will consume quantities of farinaceous puddings, often well sugared, which disengage gases readily Thirty years ago I traced a state of anæmia and debility apt to appear in colliers and others engaged in similar work to dilatation of the stomach, a dilatation due to want of home meals and to the consumption of large quantities of liquid with heavy food rich in carbohydrates Mastication must be carefully provided for and papain I have found to be a very useful aid in digestion The abuse of corsets and belts must not be overlooked In these cases rest not only after but also before meals is of importance In some emaciated persons the full Weir Mitchell system may be necessary, especially in gastroptosis, in all a long rest and change of air are of the first importance, nor should such persons on returning to their ordinary occupations expose themselves again to excessive stresses and other causes of exhaustion "

Dr N BARDSWELL (Banchory) made a communication on the subject of Dilatation of the Stomach in Cases of Pulmonary Tuberculosis As the result of his inquiries he had arrived at three conclusions 1 In cases of early disease of from three to six months' duration the stomach was normal in size and in these cases generous ordinary diet could safely be given 2 There was a tendency for prolonged over feeding to cause dilatation, and this dilatation might exist without any symptoms of dyspepsia. In the event of a relapse, however, this condition as a probable precursor of atonic dyspepsia, would certainly be a cause of anxiety Clinical experience suggested that, other things being equal, the longer such patients were kept at absolute rest (and such treatment usually implied the existence of fever) the greater the tendency to atony and dilatation. 3 Tuberculosis cases admitted with acute extensive disease would probably be some three to six months before losing their fever and consequently would require to be at rest for that period, and would run greater risks of developing atonic dyspepsia and later dilatation of the stomach than any other type of consumptive The prolonged administration of huge ordinary diets to consumptives of this clinical type, especially after the development of symptoms characteristic of atonic dyspepsia, was, in his opinion, absolutely unnecessary and unjustifiable in view of the serious prognosis which must be given when active pulmonary tuberculosis was associated with dilatation of the stomach During the past two years he had had under care eight patients (originally of the acute type of pulmonary tuberculosis now under consideration) who had previously been some six months in sanatoriums where excessive feeding was practised. In five of these patients there was definite enlargement of the stomach, and in each case this was associated with marked anorexia, dyspepsia, vomiting of yellow fluid before breakfast, and general malaise

SIR WILLIAM BROADBENT (London) remarked that his experience confirmed that of Professor Clifford Allbutt as to the frequency of the occurrences of gastric dilatation and atony It was associated in a very large number of cases with symptoms which many would regard as simple "dyspepsia" In acute rheumatism and in pneumonia he had met with a severe degree of dilatation In women who starved themselves the condition was also often met with As to the symptoms of atonic dilatation they were, in his experience largely nervous He had seen enormous degrees of dilatation atonic in origin, confirmed at an operation which had been previously overlooked because during the day the stomach [illegible]ntied itself Among the symptoms which were not [illegible] [illegible]used anginoid pains should be mentioned Th[illegible] [illegible]gina unlike true angina, was apt to come on [illegible] rest or after meals instead of after exercise [illegible] Palpitation and vertigo also resulted from dilatation The vertigo was rather an unsteadiness or feeling of loss of balance, and very often eructation of wind relieved it. Attacks of asthma at night and nocturnal symptoms of other kinds were, in his belief, usually due to dilated stomach and were probably of mechanical origin Among the proofs of the mechanical explanation was the fact that some cases got better of these symptoms when the stomach dropped Tetany might be associated with gastric dilatation and reference was made to a case in illustration. He had found that auscultο percussion and the echo of the heart sounds, especially the second sound, afforded valuable confirmatory evidence of gastric dilatation Reference was made to a case of hæmorrhage from a dilated stomach the condition having been confirmed at subsequent operation. Turning next to the question of treatment, he had been in the habit of relying on lavage of the organ with sulphocarbolate solution This should be done last thing at night in preference to the morning, for a large proportion of the symptoms arose from decomposition within the stomach at night

Professor MUSSER (Baltimore) wished to confirm in general terms the remarks which had been made by Professor Clifford Allbutt in opening the debate. He drew a distinction between atonic dilatation of the stomach with and without ptosis Cases associated with ptosis and hyperchlorhydria were often toxic or neurotic in origin, and were met with in persons of an artistic temperament and other neurotic subjects Similar cases occurred in association with sexual defects and perversions of various kinds, with which he believed gastric atony had a direct causal relation. Among the toxic conditions tobacco, tea, and various septic conditions might be mentioned. In some cases of gastric atony there might be no symptoms at all, others presented all the symptoms of neurasthenia. As a means of diagnosis he was accustomed to rely on inflation by means of a tube, but care must be taken not to distend the stomach too much. This method, combined with percussion, he had very often found trustworthy In the treatment there were many factors—the social condition, the environment, and the work of the patient—which had to be taken into consideration, and the best results were obtainable by attacking the causes

Dr T D SAVILL (London) said that he would confine his remarks to that form of gastric dilatation (gastric atony) which arose independently of organic disease, malignant or benign The diagnosis of this condition was undoubtedly very difficult, and the modern methods to which reference had been made, though difficult of application, were undoubtedly of great value The occurrence of splashing several hours after a meal when the stomach should be empty was suggestive He had found that giving the patient a draught of effervescing mineral water was a valuable aid to percussion or auscultο-percussion, and this obviated the use of the tube to which patients so strongly objected. The condition was undoubtedly more frequent than was generally suspected. He had often found it associated with neurasthenic symptoms which remained unrelieved until the gastric atony was attacked As regards the treatment he attached considerable value to two means The first was what was known as the Salisbury diet which consisted of meat only—that is to say, nutrition in a dry, concentrated and easily digestible form, without fluid at meals There were four important principles embodied in this treatment it gave the organ comparative rest, it diminished the bulk of the food considerably, and enabled the enfeebled muscular wall to regain its tone, it introduced a principle of relativity, for it was a considerable alteration in the patient's ordinary diet, and lastly, it prevented the decomposition which was so apt to take place in farinaceous food, and the consequent absorption of a quantity of fermentative toxic substances which so damaged the patient's general health Dr Savill attached great importance to the use of the galvanic current, both to the stomach and the pneumogastric nerves With, and even without, diet he had seen very marked and valuable effects produced in this way and he referred to cases by way of illustration. Drugs did not seem to be of much use, but the administration of amylaceous ferments, such as taka diastase, was undoubtedly a useful aid to other methods

Dr HARRY CAMPBELL (London) remarked that the essential cause of dilatation of the stomach was gaseous distension He pointed out that solids and liquids could not exert a pressure greater than their own weight, but that intra gastric gaseous pressure might be much greater than this, indirectly however solids and liquids might augment gaseous pressure by diminishing the space in the stomach available for gas. Hence in treating gastric dilatation a non flatulent diet should be given, and it should be as concentrated as possible. He would not inflate the stomach for diagnostic purposes if there was any cardiac failure, but he thought that the stomach might in most cases safely be blown up by bicarbonate of soda and tartaric acid and in this connexion it was useful to remember that 53 grains of the former and 45 grains of the latter yielded at the temperature of the body one litre of the gas. Dr Campbell found simple percussion a trustworthy means in a large number of cases of determining the lower gastric border auscultatory percussion had not yielded such satisfactory results in his experience. The splashing sound he did not regard as diagnostic unless it occurred from four to six hours after a meal The depression of spirits which occurred in dilatation might not be due merely to toxæmia, it might result from mechanical causes for the most profound depression would sometimes disappear suddenly upon the eructation of gas.

Dr Alfred R. Parsons (Dublin) wished to draw attention to the hydrochloric acid test as a means of detecting the presence or absence of malignant disease, and he referred to a case in which the presence of hydrochloric acid enabled him with other symptoms to exclude malignant disease as a cause of gastric dilatation. The absence of hydrochloric acid was not of itself distinctive of cancer for it might occur in Addison s and other diseases. Splashing four to six hours after a meal was a valuable aid to diagnosis of gastric atony He made reference to two cases of tetany associated with gastric dilatation. One of these cases raised the question of the value of operation in some cases of gastric dilatation

Dr A. Mantle (Halifax) made reference to the neurovascular supply of the stomach and expressed the opinion that a study of the anatomy of this region might explain many of the symptoms. These patients often complained of coldness of the extremities. He thought that tobacco-smoking might be included among the causes. Rest was an all important factor in the treatment and he referred to a patient in the Halifax Infirmary

Dr W Calwell (Belfast) thought that it was very difficult to distinguish minute refinements of differences in the size of the stomach. He referred to bolting of food as a cause of dilatation and mentioned a case in point. Most cases of gastroptosis were associated with some change in the secretion of hydrochloric acid. Dr Calwell attached considerable importance to the estimation of the hydrochloric acid. If there were excess of free hydrochloric acid it pointed strongly to gastric ulcer If it were absent when examined on two or more occasions the case was probably malignant. He had found less difficulty in the use of the tube than had some of the other speakers, and he regarded its use as a very valuable adjunct to the diagnosis

Dr W Page May (London) showed some lantern slides of Tracings obtained in an Investigation on the Movements and Innervation of the Stomach carried out last year in the physiological laboratory of University College, London chiefly on anæsthetised dogs and monkeys. The tracings showed that the gastric tone and movements were largely dependent on the extrinsic nerves of the stomach—notably the vagi and splanchnic nerves. Stimulation of the vagus produced diminution of the gastric tone and movements followed by an increase. Anæmia artificially produced by blocking the thoracic aorta effected a diminution of the gastric tone and movement. Stimulation of a sensory nerve, as shown by previous observers, produced a similar effect. Therefore it was natural to conclude that disorder of the extrinsic nerves of the stomach must influence and in many cases favour the production of atony or dilatation of the stomach.

Sir W Mitchell Banks (Liverpool) read a paper on a successful Case of Gastroplication of the Stomach. The patient was a man, aged 36 years who was admitted to the Liverpool Royal Infirmary in October 1899 He had been a cavalry soldier and had drunk hard while in the army For three and a half years previously to admission he had suffered from a very aggravated degree of symptoms referable to the stomach which no treatment would alleviate. Dietetic treatment and systematic lavage were tried without effect and on Nov 10th, 1899 Sir W Mitchell Banks removed a strip from the anterior wall of the stomach six inches long by three inches broad. The patient made an excellent recovery he had been seen at frequent intervals since and had derived very great benefit from the operation. All his old symptoms had disappeared It was of great importance to watch these cases after operation before deciding the verdict as to cure and that was why this case had not been published before Such operations were generally described as operations of complaisance"—i e., were not necessary to save life. But in this case the patient would probably have died without the operation. Sir W Mitchell Banks concluded by giving an outline of the history of the operation and discussing the relative merits of the different methods, and he again emphasised the necessity of prolonged observation before coming to a conclusion as to the result.

Professor Carl von Noorden (Frankfort-on Main) read a paper on the Dietetic Treatment of Chronic Granular Kidney giving a preliminary report on his investigations on the excretory power of the diseased kidneys. He did not consider that the administration of such drugs as iodide or salicylic acid gave a true test of the excretory power of the kidneys, nor was the hypodermic injection of phloridzin of use in this respects for none of these substances gave a true index of the power of kidneys to secrete urea and the natural constituents of the urine. The functional power of the kidneys could only be measured by an exhaustive chemical examination of the urine. As a result of his inquiries he had come to the conclusion that although nitrogenous substances should be given in only limited quantities in acute renal disease a fairly liberal amount might be allowed in chronic renal disease. The amount of water allowed to be taken might be one and a half litres per diem but more than this was not desirable More fluid than this threw too much work on the heart, which was always damaged in these cases. In regard to the nature of the solid food he had not found red meat any more harmful than the white flesh of rabbits and chicken. Marienbad and Carlsbad treatment was distinctly unsuitable for cases of chronic Bright s disease. His investigations went to show that these cases wanted plenty of strengthening food, not a lowering diet, and such patients did much better under immediate medical supervision in hospitals or sanatoriums

---

SURGERY

Wednesday July 30th

After a few opening remarks by the President of the Section Mr James Hardie (Manchester) a

Discussion on the Treatment of Inoperable Cancer

was opened by'

Mr Henry Morris (London) who first defined what he meant by cancer and the term inoperable. There were for practical purposes four groups of inoperable cases (1) primary cancer affecting inaccessible parts or vital organs (2) primary cancer which, although at first removeable, had advanced beyond the limits within which a local operation was prudent and complete removal possible (3) certain cases of acute diffuse carcinoma and very rapidly growing or widely infiltrating new growths of exceptionally virulent character and (4) recurrent carcinoma where the disease had recurred in many places or in parts where it was impossible to reach it. He described the treatment employed for these cases criticising the methods under the two following heads (*a*) the employment of remedies and methods other than the knife to cure, to ameliorate, or to retard the disease as well as to prevent relapses after its removal, or (*b*) the employment of the knife to give relief from pain to prolong life to restore function and otherwise to make the patient's condition more tolerable. Comparisons were drawn between the results of treatment with Coley's fluid and Beatson s treatment and then the modern physical methods of treatment were fully considered. First, Finsen s light treatment for rodent ulcer second the treatment of malignant disease by the high frequency currents third the treatment of rodent ulcer with the x rays and fourth the treatment of sarcoma and carcinoma with the x rays. After a careful review of these methods he arrived at the following conclusions. 1. That the serum treatment of malignant disease is not of the slightest use in carcinoma that not one-half of the cases of spindle celled sarcoma disappear under treatment with Coley s fluid that in cases of sarcoma, other than the spindle-celled Coley s fluid is not of value, and that the treatment by Coley s fluid has many dangers and should never be employed except in absolutely inoperable cases. 2. That Beatson s treatment is limited in its action to cases of mammary carcinoma, and the local and glandular recurrences after mammary carcinoma, and that even in these cases only a small proportion are influenced by the treatment, whilst neither as a cure nor as a palliative can it be relied upon in any given case 3 That rodent ulcer has in Finsen's light and in the x rays its most successful treatment, so far as we know at present, and that this is true not only of cases otherwise inoperable, but also of operable cases, because of their excellent cosmetic results and of their effect upon insidious and non-evident foci There are, nevertheless, cases of rodent ulcer which resist the light and the x rays treatment, and some of these cases are successfully treated by excision and caustics 4 That sarcoma, epithelioma, and the other forms of carcinoma are best treated, whenever possible, by early excision, and that all forms of treatment hitherto tried in inoperable cancers of these kinds are uncertain and inconstant in their effects and untrustworthy as to the durability of the results they produce In the vast majority of cases they are quite without palliative influence of any kind, except possibly in relieving pain. 5 That the boundary line between what are considered operable and inoperable cases needs revision from time to time, that the tendency to extend the limits of operable cases needs in some instances to be restricted, and in others possibly there may prove room for fuller extension 6 That it is open to question whether some of the operations performed for relief or prolongation of life in inoperable cases of malignant disease should not be abandoned and whether in other cases palliative operation ought not to be more often performed 7 That investigations into both the cause and the nature of cancer are of the first importance as being more likely to lead ultimately to the cure than excision 7 That with few exceptions the attempts to cure cancer by means other than early and free operations have been hitherto almost invariably futile 9 The complete ignorance as to the cause, nature, and curative treatment of cancer has long pointed to the necessity of instituting a comprehensive collaborative, and coöperating inquiry into the whole question of malignant disease, and that it was a source of great satisfaction to know that at last, though with great difficulty sufficient funds have been raised to enable the two Royal Colleges to make, at any rate, a beginning in this wide reaching and unspeakably important subject It was devoutly to be hoped, albeit it may be too sanguine to expect, that the result of these researches may be to discover, not only the cause and curative treatment of cancer, but the means of its prevention as well

Dr G T **BEATSON** (Glasgow) said there were two points upon which emphasis should be laid in dealing with the question one was the capriciousness of carcinoma and the other that there was such a thing as a spontaneous cure of cancer In spite of these facts, early, bold, and free removal of the disease was the only primary treatment that could be recommended But by such cases of spontaneous cure an element of hope is introduced The non operative treatment of carcinoma naturally falls under two headings—the general and the special The general treatment is to ward off the common causes of death in such cases, to alleviate pain, &c. In connexion with the latter he had had much success with the administration of phenacetin in doses of from 10 to 15 grains thrice daily There were no bad effects from it and he thought morphia should therefore be avoided. With regard to special methods in the treatment of inoperable carcinoma he considered a generous diet as essential, that thyroid extract was the drug which seemed to have the most marked effect, altering, he believed, the relation between epithelium and the lymphatic system, the thyroid stimulating the latter It must be given in suitable doses. He had tried up to 250 grains daily, but considered small doses of from three to five grains three or four times daily as the best. With regard to x rays, they had to be very carefully handled With care undoubtedly good results had been seen but harm may develop on account of the reaction which may be induced He alluded to some cases in which after x ray treatment sudden œdema and other serious symptoms occurred The method of oöphorectomy he was anxious should be judged entirely on its merits He had never mentioned ' cure" in relation to it, but the treatment was placed before the profession because he felt that they should review its effect themselves After watching the matter closely now for several years he had come to these conclusions At present oöphorectomy was only applicable in carcinoma originating in the mamma, it was not contra-indicated after the menopause, but the best results seemed to occur after 40 years of age. It was impossible to say in what cases the benefit would arise, but slow-growing cancer yielded most readily Further, large as well as small nodules would disappear in favourable cases, but visceral and bony deposits remained unaltered while lymphatic glandular growths underwent retrogressive changes. These almost invariably gave relief from pain and improvement of general health That in some instances there was only a transient benefit and fresh nodules appeared while in others relief has been obtained from four to five years. Oöphorectomy was certainly not to be used as a substitute for free local removal, but he believed that it had done no harm in its performance, and it does give some evidence of the lines on which to work and to investigate'

Mr **THOMAS BRYANT** (London) dwelt chiefly upon the effects of x rays, with which he had had some happy experience He considered that they should be employed in all cases of inoperable carcinoma but not to take the place of the knife in those suitable for operation The rays alleviate pain and cause the disappearance of nodules and ulceration He related cases of pure recurrent carcinoma of the mamma which had been greatly benefited In one case a cystic change had occurred in the nodules, the spaces containing a mucoid material indicating metabolic changes in the cancer cells. In another, distant lymphatic gland swellings had vanished with only a local application of the rays to the recurrent growth itself He had had good results in a case of carcinoma of the rectum and another of cancer of the uterus in which the rays were applied, but without the aid of a speculum. Such results should not be stated as a cure

Professor R. B **WILD** (Manchester) spoke from the point of view of a physician with an experience of 10 years, in which he had seen undoubted cases of spontaneous disappearance of cancer growths. He had tried many of the newer methods of treatment of inoperable malignant growths Coley's fluid was of no use in carcinoma and in advanced cases of sarcoma there was grave danger of reaction, which might be serious Thyroid extract, even in small doses, in advanced cases seemed to have a bad effect, causing loss of weight, &c, although the cancerous growth might shrink. Arsenic he had given largely and in many forms, but had seen no benefit whatever The best non-operative treatment was to relieve pain and to maintain nutrition He believed in opium first and phenacetin second for the former purpose. When morphine had to be increased to large doses he omitted it altogether for a week, giving hypodermic injections of $\frac{1}{6}$th of a grain of hyoscyne in place of it, and then restarting morphine in small doses He considered that morphine improved nutrition and that the exhibition of doses of alcohol did the same

Mr W F **BROOK** (Swansea) said that the results of x ray treatment were most encouraging in some cases and most disappointing in others He had seen good results in epithelioma of the scrotum and no improvement in some cases of epithelioma of the lip He had performed proctotomy and applied x rays directly to the growth without any benefit. But he had seen good in cases of carcinoma mammæ particularly in one patient, whom he showed to the section in which after 41 sittings the growth had clinically gone, a goitre in the same patient being entirely unaffected. The value of x ray treatment he believed to be fully established, but it was impossible to predict in what cases good would follow He thought that in some instances the application of x rays might advantageously precede local operative treatment.

Mr F B **JESSETT** (London) was convinced of spontaneous cure of carcinoma and cited cases of it. He had had experience of five cases of oöphorectomy In two there had been a relief of pain but in none could he say there was an appreciable diminution in the growth. One case of oöphorectomy in a woman without cancer developed it in the mamma five years after the laparotomy He was disappointed with the result of x ray treatment except in some cases of rodent ulcer

Dr B G **FERGUSON** (Cheltenham) had recorded one of the earliest cases of x ray treatment of recurrent carcinoma, in which 20 applications had caused the growth utterly to disappear No reappearance came for eight months, when some nodules were seen. Another series of 20 applications caused their removal as well as that of some glands in the axilla. He would not advise commencement of treatment by the rays but free removal by the knife. In rodent ulcer good results had followed the use of the rays. Incidentally he mentioned the benefit which had followed their application in sinuses after nephrectomy. He had used chloride of zinc paste in carcinoma with satisfactory results.

Dr LOVELL DRAGE (Hatfield) advocated the use of cinnamon of sodium in glycerine by hypodermic injection. Half-drachm doses of the glycerine solution caused no unpleasant symptoms but a marked relief from pain.

Dr HERBERT SNOW (London) agreed as to the local incidence of cancer, the corollary to which was that primarily inoperable cases ought to be few and far between. He did not believe in any instances of spontaneous cure; all these must be placed in the category of mistaken diagnosis. Nodules on the thorax after removal of carcinoma might seem to disappear but they were always there though less apparent. Early and free removal should prevent their occurrence. He had seen oöphorectomy performed 10 or 12 times. Two or three times brawny œdema had disappeared but in another two cases chronic insanity had supervened. He did not believe in the value of x ray treatment, referring the apparently good effects to mental impression and the burning action of the rays. Opium was not lethal to cancer cells but it was nevertheless of great benefit. It should not be pushed to great doses and at the same time all means should be adopted which diminished the force of the heart and equalised the circulation. In this matter he strongly deprecated the use of alcohol. Cocaine should be combined with morphine when intestinal cancer was present. He sincerely believed in the destruction of cancer cells by the lymphatic gland tissue.

Dr H. MANDERS (London) referred to the treatment by high frequency currents and desired that failures as well as successes should be reported if progress was to be made. In carcinoma the elimination of urea was markedly lessened and the effect of the high frequency currents was to increase metabolism as evidenced by the increased percentage of urea passed. These currents also had a bactericidal action and if carcinoma was due to a parasite, which he thought highly probable, they might act in this manner also. The body itself governed the oscillations of the high frequency currents and the tissues had a different relation to them in health and disease.

Mr J. PAUL BUSH, C.M.G. (Bristol), said that his experiences in the x ray treatment had been most disappointing, for he had not as yet seen any case of undoubted carcinoma in which the improvement had been of a permanent nature. He further believed that Coley's fluid might be a very dangerous material to use.

Mr J. D. MCFEELY (Dublin) alluded to cases of advanced rodent ulcer in which he had obtained most satisfactory results from the free use of pure formalin applied with the patient under an anæsthetic on account of the severe pain during the actual treatment.

Mr ALEXIS THOMSON (Edinburgh) presented to the section an elaborate analysis of the cases of oöphorectomy published up to the present in British medical literature.

The following papers were taken as read:—

Mr J. PAUL BUSH, C.M.G.: The Treatment of Deformities of the Face by the Subcutaneous Injection of Paraffin.

Dr J. WALKER DOWNIE: Injection of Paraffin in Nasal Deformities.

Mr E. STANMORE BISHOP: Methods of Uniting Divided Intestine, with special reference to a new Bone Bobbin for that purpose.

Professor F. VALENTINE (New York): The Diagnosis of Urethral Disease.

PATHOLOGY

WEDNESDAY, JULY 30TH

The PRESIDENT, Professor Sheridan Delépine (Manchester), said that valuable time would be saved if the section would proceed at once to the business of the day.

Dr FREDERICK W. MOTT (London) opened a discussion on

The Pathology of Nerve Degeneration,

confining his remarks principally to the chemical aspect of the subject. The first part of his paper had already been recorded in his Croonian lectures of last year and embodied his researches in the chemistry of the Marchi staining method. He found that the amount of phosphorus in the spinal cord, after section of a peripheral nerve (the sciatic) varied inversely as the black staining of the cord with Marchi's fluid. He concluded from this that the lecithin of the normal nervous tissue was split up into fat and glycerophosphoric acid. The evidence of the change was to be found in the presence of choline in the cerebro-spinal fluid. Turning to the clinical aspect of these researches he had found that choline was increased in the blood in general paralysis, beri beri, and other nervous diseases, and he suggested that this increase of choline might be used as a test for the presence of organic disease of the nervous system where a doubt existed between this and functional disease. In the second part of his paper Dr Mott expressed his suspicion that stimulus from nerve cells might play an important part in nerve regeneration. This stimulus was excluded by cutting the posterior nerve roots when he found that regeneration took place less readily. He believed that the neurilemma cells were important factors in the regeneration of the axis cylinders.

Dr JUDSON S. BURY (Manchester) remarked on some of the clinical aspects of peripheral neuritis. He drew attention to the acuteness and severity of some cases which presented the type known as Landry's paralysis and also to the curious persistency of many cases of neuritis, however caused, even when the degree of neuritis was obviously slight.

Dr A. WILSON said that the earliest changes in the fibrillæ consisted of a loss of the capability of staining with such dyes as toluamine blue. It was important to know that the dye entered into combination with the tissue to form a salt. In degeneration this faculty of forming a salt with the dye was gradually lost. In referring to the neuron theory he said that the degeneration of a severed neuron must cease at the end organ of the nerve. If it passed beyond this the cells affected were not a part of the neuron and the theory fell to the ground. He illustrated the degeneration spreading beyond the end organ of the nerve by section of the glosso-pharyngeal nerve in which the end bulbs of taste disappeared.

Dr J. PURVES STEWART (London) referred to Waller's paper in 1850 and Ranvier's work in 1873. He showed on the screen sections of nerves in the chief stages of the process of degeneration. Degenerative changes occurred in the distal segment of a divided nerve whether it was sutured immediately or not. Primary union without degeneration did not occur. The degenerative changes also affected a small part of the proximal segment in the neighbourhood of the wound of division. The cellular changes in degeneration consisted of a transient invasion of leucocytes which were later replaced by connective tissue cells which at the end of five weeks had absorbed all the myelin. These connective tissue cells were then replaced by proliferated neurilemma cells which became elongated and ultimately formed fibrous tissue. The neurilemma cells began to proliferate on the second day after the injury and arranged themselves in longitudinal columns with overlapping protoplasmic processes. Fragmentation of the medullary sheaths and axis cylinders began on the fourth day. Regeneration overlapped degeneration in point of time. In the distal segment of a reunited nerve, spider cells shot out axis-cylinder processes from their opposite poles at the end of three weeks. These neuroblasts were the neurilemma cells and the threads fused into a continuous axon. The new medullary sheaths were similarly formed from the neurilemma cells. In a nerve five months after immediate suture the nerve fibres appeared practically normal. In the distal segment of a non united nerve the process of regeneration was essentially the same but the new nerve fibres did not attain full maturity. The well known end bulb of the proximal segment was formed at first by the curling back of the ends of the divided nerve fibres and subsequently there was a disposition of new axis cylinders and medullary sheaths from the proliferated neurilemma cells. The deduction from these facts was that since regeneration occurred in the distal segment of a non united nerve the so-called "neuron" theory of Weldeyer could no longer be maintained. The speaker would substitute the fibrillar theory of Apathy according to which the nerve fibrils were the essential elements of the nervous system. The nerve cells acted as convenient shunts and the central nervous system was one vast exchange transmitting nerve impulses from one part to another. The central nervous system, however, exercised a profound influence on the peripheral nerves without which the new fibres of the distal segment did not attain maturity. Two factors were, therefore, necessary for the complete regeneration of a nerve fibre: (1) the presence of neurilemma cells; and (2) the re-establishment of conduction of impulses to and from the central nervous system.

Professor C S SHERRINGTON (Liverpool) said that to quote degenerative changes in muscle and gland as results of section of peripheral nerves was no valid argument against the neuron theory The view advanced on what appealed to them as urgent grounds by Dr Purves Stewart was not in the least incompatible with the neuron theory It merely made the peripheral nerve fibre a chain of neurons instead of a single neuron and explained the degeneration of the links at the peripheral end of the chain as due to the same kind of influence by one neuron upon another as was exerted by neurons upon striped muscle fibres

Sir VICTOR HORSLEY (London) spoke in support of the neuron theory He considered the changes described by Dr Purves Stewart to be those of nutrition In Gowers's tract the spino-cerebellar part never degenerated downwards. He found that in regard to this tract the neuron theory was borne out. If the superior cerebellar peduncle was divided in a cat the coarse fibres degenerated towards the brain, the fine fibres towards the cerebellum

Dr MOTT replied

Dr D CHALMERS WATSON (Edinburgh) gave a kinematograph and lantern demonstration on

Nervous Diseases in the Lower Animals

The animals shown on the screen were a puppy and a horse. The former had suffered from paralysis, ataxia, altered sensibility, and other symptoms, the gross morbid lesions found at the necropsy were those of imperfect development of the brain convolutions and chronic hydrocephalus The latter was a case of stringhalt and an exhaustive histological examination showed advanced morbid changes in the nervous system and elsewhere, the origin of which was probably bacterial.

A lantern demonstration of specimens from a case of Arrested Development of the Olivo pontine Cerebellar Complex accompanied by Spina Bifida and other Developmental Peculiarities was given by Mr KEITH W MONSARRAT (Liverpool) and Dr W B WARRINGTON (Liverpool)

Dr WARRINGTON read a paper on the

Anatomy of the Nervous System in a Case of African Lethargy,

and showed sections of the pathological conditions present. The pathological process was one of subchronic leptomeningitis The characteristic pronounced feature was perivascular infiltration of round cells. No one part of the brain was more affected than another His examination of the nervous system agreed with Dr Mott's description of these cases There were no micro-organisms similar to those recently described

Sir VICTOR HORSLEY and Dr MOTT discussed the paper and Dr WARRINGTON replied

---

DISEASES OF CHILDREN

WEDNESDAY, JULY 30TH

Professor T M. ROTCH (Harvard University) opened a discussion on

The Modification of Milk in the Treatment of Infants

In an elaborate paper supported by numerous statistical tables he urged the necessity in the consideration of this question of securing terms having a definite and universal significance. Conflicting opinions were, he considered, due, at least in part, to the absence of precise and exact definition, and in any case it was a necessity for profitable comparison and discussion that all should attach one and the same meaning to each of the terms to be employed. The exact analytical methods of modern chemistry rendered this now possible, and the question of infant feeding ought therefore to be removed from the region of vague generalisations to the exact domain of percentage compositions The physician ought to free himself from the empirical methods of the nurse and from the tyranny of the manufacturer of artificial foods and to prescribe the nutrition of his infant patients with the same exactness and knowledge which he adopted in the administration of drugs There could be no doubt at all that the best food for young infants was the natural supply of breast milk, but it was equally certain that circumstances of various kinds compelled the physician not infrequently to find a substitute for this. And in this endeavour it was necessary to remember that human milk differed widely in its quantitative composition. To copy nature's processes successfully, therefore, the physician must be able to vary the percentage of proximate principles in the substitute food he prescribed according to the requirements of the individual infant—a principle important in health but still more important in the treatment of disease. There was no dispute that a substitute food must be the milk of some animal. The difficulties of the question arose from the fact that every such milk for purposes of infant feeding required modification Such modification was usually effected by a rough empirical method It was desirable to replace this by precise and definite processes so that the physician should be aware of the percentage composition of the nutriment ordered for the child and should be able to vary this from time to time as might be necessary The first essential was to secure pure milk of good quality, of known quantitative value, and free from bacterial contamination, the second was the safe transmission of such milk without change from the source of supply to the individual infant, and the third was the capacity to vary the composition of the food as the judgment of the physician directed To secure this programme every step in the process must be under medical supervision. Professor Rotch then gave a graphic account of the organisation of the milk-supply in connexion with the Gordon Walker milk laboratories He described the feeding, toilet, and housing of the cows, the steps taken to prevent contamination, and the methods employed to provide milk of known composition As a result of these the laboratories were able to supply milk with various percentages of fat, carbohydrates, and proteids, and similarly to adjust as might be required the relative proportions of the caseinogen and whey proteids The physician therefore prescribed the food of the child with the same confidence that he sent directions for drug treatment to the pharmacist. The milk laboratory and store were conducted with the same intelligence and care as ruled the conduct of the pharmacy It had been found readily possible to convey milk obtained as described even 1000 miles without change and without prejudice to its nutritive value And, further, by certain modifications of method the same principles might be adopted in the home. To obtain pure milk for infant feeding was the desire of all, to imitate the natural supply modification in some degree was an admitted necessity, and to conduct that modification on scientific principles could only be accomplished on a quantitative basis. Professor Rotch argued that these ends could only be obtained by some such methods as he had described and concluded by stating that actual experience of large numbers of physicians in America had proved these methods to be both theoretically sound and practically successful.

Dr JULES COMBY (Paris) discussed the question in detail and suggested some doubt of the influence of artificial processes on the nutritive value of milk.

Professor A. BAGINSKY (Berlin) had listened to Professor Rotch's description of the dairy farms and milk laboratories with much sympathy and interest, as he had for some years been organising similar methods in Germany He approved of the principle of prescribing milk of known composition, more especially in cases of disease, but thought that the widespread use of artificially prepared milk might be responsible for results not advantageous to infant health and vitality

Dr H DE ROTHSCHILD (Paris) could not admit that there was any wide field of usefulness for artificially prepared milk. Healthy children were readily nourished on pure cow's milk, and this by appropriate dilution could be adapted to most cases of disease The essential thing was to be able to purchase pure milk, and granted this, all the necessary preparation could be conducted at home under the physician's directions. He, however, entirely sympathised with the suggestion to bring the animals yielding milk for feeding infants under medical supervision

Dr W P NORTHUP (New York) in an energetic speech offered his experience as a practical physician in support of the value of Professor Rotch's methods All were agreed that pure milk was desirable, and this was exactly what the laboratories secured. They could order it and be sure that they would obtain what they ordered—milk chemically pure, with bacteria in limited numbers, and practically free from toxins But it was necessary, and more especially in cases of disease, to secure food adapted to the individual infants' requirements and the opportunity of obtaining this in an exact fashion he regarded as a triumph of American medicine

Dr GEORGE CARPENTER (London) approved of the principle of prescribing milk of known composition and had every sympathy with efforts to obtain this The question of expense had to be considered and he feared this was a practical difficulty of moment. The condition of milk farms was often deplorable and was responsible for many epidemics. In discussing artificial feeding it was necessary to remember that a good wet nurse was often the best solution of the difficulty

Dr ERIC PRITCHARD (London) urged that the less interference that milk used for infant feeding was subjected to the better The fact that the mother's milk varied from time to time was an argument against too severe and rigid a standard in preparing a substitute milk. He had tried the Gordon Walker Laboratory in London but had found the expense and the delay in supplying what was ordered to be serious objections. If cream of known strength could be obtained all necessary modifications in the milk required by infants could be executed at home and without the aid of a laboratory

Dr JOHN THOMSON (Edinburgh) had no practical experience of the laboratory preparation of milk. In the cooler climate of Scotland such methods were perhaps less necessary

Dr F M. SANDWITH (Cairo) heartily supported the plan advocated by Professor Rotch. He spoke of its value from personal experience. The method and its results could not be too highly praised.

Professor J W BYERS (Belfast) spoke in a similar strain. He looked upon the discussion as distinguished by a proposal of great value in the management of infants whether healthy or sick.

Professor ROTCH, in reply agreed with those who argued that the food of the infant needed variation but he preferred exact to haphazard methods of securing this. As milk must be modified, why not modify it scientifically? His position was that if possible the mother should nurse her own child, that the best substitute was a healthy wet nurse and that, this failing milk carefully collected of exact composition, and suited to the individual s requirements should be prescribed. His proposal was not to substitute artificial for natural feeding but to make the former when it was required, an exact instead of a chance proceeding He had visited the Gordon Walker laboratory in London and was sure that, if supported by physicians, it would give exactly what was required. The question of expense—and this had been alluded to in somewhat exaggerated tones—would not be allowed to block a reform which concerned the well being of infant life and growth.

DERMATOLOGY

WEDNESDAY JULY 30TH.

The PRESIDENT of the section (Dr Henry A. G Brooke) opened the meeting with a few preliminary observations He expressed his regret that several guests of the Association who would have read papers or taken part in the discussions were prevented from being present, and he referred especially to Professor Neisser of Breslau, Dr Brocq and Dr Freund He hoped that Professor T. C Gilchrist of Baltimore would be able to attend on Thursday to give a demonstration of blastomycetes He welcomed Professor Gilchrist for he was an alumnus of the Owens College and a former pupil of his own. The Johns Hopkins University of Baltimore was well equipped with research laboratories so that the younger dermatologists were able with ease to undertake researches without incurring great expense. It was essential that they should have such facilities as these in this country and though it was hopeless to expect the Government to do anything in the matter they might not unreasonably expect something from private munificence, for Liverpool has just received £10,000 for a bacteriological laboratory

Radiography X Ray Treatment High Frequency Method, and Light Treatment

In the absence of Dr L. FREUND (Vienna) the Secretary (Dr G H. LANCASHIRE) read a summary of Dr Freund s paper The main conclusions at which Dr Freund had arrived were as follows. All radiant phenomena have the same physical basis and the effect of rays on the body varies like that of chemical agents, with the dosage and may range from mere stimulation to actual destruction of tissue In weak doses the rays favour organic processes, such as the growth of hair and the production of pigment. In stronger doses they lower vitality and produce inflammatory reaction. The clinical effects of all forms of radio-therapy are similar The physiological effects are in direct proportion to the intensity of the raying but in inverse proportion to the wave lengths. The reaction appears after a latent period, the length of which is inversely proportional to the wave length and intensity of the raying Those rays which have the property of exciting fluorescence are physiologically the most powerful. High frequency currents can also be included in radio-therapy and Dr Freund believes that the physiological effects of this method are due solely to the spark-discharges High frequency currents appear to be useful in pruritus and in lupus erythematosus. X rays are of value in some cases for the removal of hair as in ringworm favus, sycosis, and hypertrichosis, but in lupus and in epithelioma the improvement is due to cell infiltration and proliferation, and to the influence of the x rays in promoting the formation of connective tissue and cicatrices, but they possess no bactericidal properties In lupus vulgaris Finsen's light treatment and the x ray method are equally good, both take about the same length of time, and the cosmetic results of both are equally good. A rational method is first to x ray large surfaces and then to treat the remaining foci with Finsen s apparatus. Hard tubes are less likely to cause dermatitis and if it does occur it subsides more readily Ultra violet lamps have not superseded Finsen s lamp, for the latter has a greater penetrating force.

Dr SEQUEIRA (London) agreed with many of the opinions which had been expressed in Dr Freund s paper With regard to the treatment of rodent ulcer he thought that in suitable cases wide excision was the best possible treatment, but in extensive cases x ray treatment was of great value. Recurrence was common after the use of x rays, but a further application of the treatment sufficed to remove the recurrent nodules. Of 80 cases of rodent ulcer 34 were cured and most of the remainder were still under treatment. Some of the earlier cases had remained free from recurrence for 18 months. Unfavourable conditions for x ray treatment were involvement of cartilage, periosteum, or bone perhaps mainly from a mechanical hindrance to healing Sometimes the hard margin refuses to disappear, in such case a low tube may be employed to cause great reaction, or the actual cautery may be used. In cases of true epithelioma improvement may occur but when the lymphatic glands are involved the x rays seem to be powerless. Recurrent nodules of carcinoma in the skin, as after amputation of the breast, may disappear but the glands are less easy to affect. Lupus may be cured by the x rays but relapses occur again and again The effective factors are the x rays themselves, for the interposition of an aluminium sheet does not interfere with the effect. After x ray treatment disfiguring telangiectases were not infrequently left. In lupus erythematosus x ray treatment was valueless.

Dr S. E DORE (London) had employed Finsen s light treatment for two years in conjunction with Mr Malcolm Morris. He considered it important not to over-estimate the value and the possibilities of the treatment. The chief advantage is the excellence of the results and a case may be treated indefinitely without the risk of any disfigurement. The application of pyrogallol or acid nitrate of mercury to the patches greatly increases the activity of the light. Blue rays are of more importance than the ultra violet rays.

Dr J M H. MCLEOD (London) described some experiments he had been making to obtain an increase of the reaction after Finsen s light treatment. The liquids he found to be specially useful were (*a*) a 1 per cent. solution of potassium permanganate, (*b*) a weak solution of iodine with glacial acetic acid and (*c*) pure carbolic acid. He had tried Finsen treatment in five cases of lupus erythematosus, in two there was a definite improvement, two were unaltered, and in one case the disease was certainly made worse.

Dr LESLIE ROBERTS (Liverpool) was of opinion from some observations he had made that the local inunction of mercury and the application of the biniodide of mercury in an etherial solution of soap was more effective than Finsen treatment.

Mr J F HALL-EDWARDS (Birmingham) thought that unless a reaction was produced x rays did no good. Hard tubes are best, and much reaction is produced if the tube sparks over" The effect is probably electrical

Dr P S ABRAHAM (London) considered x rays to be especially useful for lupus of the mucous membranes. He had cured an extensive case of lupus erythematosus by means of x rays but some cases of this disease are distinctly made worse by x rays.

Mr CHISHOLM WILLIAMS (London) spoke on High Frequency Currents He felt sure that the beneficial effect was not due to "sparking" for he had seen removal of a lupus of the face by the application of high frequency currents to the foot—i.e., a general electrification was produced. High frequency currents acted as a general tonic.

Dr G G **STOPFORD TAYLOR** had had remarkable results after the application of x rays to cases of rodent ulcer and epithelioma. The application of pyrogallal greatly enhances the effect of Finsen treatment.

Mr **GEORGE PERNET** (London) had found the Lortet lamp very tedious at University College Hospital.

Dr **NORMAN WALKER** had noticed the hair grow in two cases while under the x ray treatment. In sycosis the hairs were not merely removed but much reaction was produced, and permanent benefit followed. He had been much disappointed in the results of the light treatment in lupus, it was extremely tedious, but he had been pleased with the x rays. Iodide and carbolic acid greatly assist in the production of a reaction. Lupus erythematosus reacts severely to x rays, but in many cases improvement follows. In rodent ulcer excision is the proper treatment, but if that be impossible the x rays may be used with benefit. During the last month he had treated a case of mycosis fungoides with striking benefit, which was noticeable after three exposures to x rays, all the nodules had flattened down. He did not consider the ultra violet lamp to be any improvement.

The **PRESIDENT** had also seen marked improvement in a case of mycosis fungoides under the influence of x rays.

Professor R B **WILD** (Manchester) thought the x rays of much value in the treatment of lupus and remarked that it was not always the most superficial nodule which responded best to treatment. When excision is done for rodent ulcer care should be taken to remove the growth deeply as well as extensively. X rays often gave very good results in rodent ulcer, but not if cartilage is exposed on the nose or ear. X rays are not always free from danger, for he had known in one case that a panophthalmitis had supervened necessitating the removal of the eye.

Dr **LANCASHIRE** (Manchester) considered it important that the dermatologist should be acquainted with the physical aspect of the question. He was inclined to think that the x ray tube was only a means of giving a brush discharge.

The **PRESIDENT** mentioned a small point of some value. Small refractory nodules could be made to disappear readily by superficial scarification.

Mr **GEORGE PERNET** and Dr H **RADCLIFFE CROCKER** (London) read a paper on the Use of Tuberculin T R. in Lupus Vulgaris. There was no doubt that to a certain extent tuberculin T R is beneficial, especially in the ulcerating forms in young people, but it was of little value in the nodular forms in old people. The best results follow the bowel injection of the tuberculin, and other methods of treatment, such as scraping and the administration of thyroid extract, assist. On the whole tuberculin T R cannot be recommended, for the method is expensive, tedious, and painful.

PHARMACOLOGY

WEDNESDAY, JULY 30TH

The **PRESIDENT** (Dr Nestor Tirard, London) delivered an interesting introductory address, in which he especially alluded to the loss suffered in the death of Dr Daniel Leech. The time and place for this appreciation of Dr Leech were well chosen. Dr Tirard said that presidential addresses were distinctly to be deprecated, the time for work was limited, the amount of work was large. With kindly forethought presidents of sections were warned not to occupy more than 15 minutes if they wished to make any introductory remarks. With the programme before them he would necessarily respect the wishes of the meeting by being as brief as possible. Indeed, he would not have occupied time at the commencement of the meeting had he not felt that the section of pharmacology, meeting in Manchester, must commence with some thoughts on the late Professor, Dr Leech, who worked so enthusiastically at the Owens College and whose work broadly conceived had had such a wide sphere of utility. He used to say with pride that the Victoria University was the first to examine in this subject and he was remembered within those walls, within this kingdom, and in all parts of the Empire as one who laboured to substitute the science of pharmacology based upon experimental investigations, for the loose therapeutic statements which had previously governed so much of the literature relating to drugs and their actions. Dr Leech would be remembered as a practical physician who found time to initiate and direct research, even when the claims upon his time did not allow him to carry out all the details. He was one who did not shrink from personal experiments with drugs. Dr Tirard remembered the amusement and admiration which Dr Leech excited at a committee meeting by exhibiting his forearm marked by blisters raised from cantharidis and mylabris. His interest in the British Pharmacopœia led him to continue experiments right up to the time when printers were clamouring for the final revise, and almost before the volume was issued he was arranging fresh investigations which might lead to wholesale revisions of what had just been authoritatively established by the General Medical Council. The British Medical Association would remember also that in his desire to respect the clinical experience of the medical profession he initiated in 1894 a laborious inquiry into the frequency of employment of various drugs which were perhaps discredited by many teachers unable to explain their actions by experiment. In that inquiry every member of the Association was given an opportunity to record a vote which would influence the construction and composition of the new British Pharmacopœia. Even shortly before the end, when he was too ill to attend to other work, he still struggled to consolidate the arrangements which he had made for the future of the Pharmacopœia, arrangements calculated to secure greater uniformity, greater scientific accuracy, and more general respect. At the Owens College his memory and example were perpetuated in the professorship which bore his name. Dr Tirard concluded by saying that having been himself intimately associated with a large part of Dr Leech's pharmacopœial work, he could not preside in that section of pharmacology in that college without having his mind filled with thoughts of his old friend.

Sir **LAUDER BRUNTON**, F R S, opened a discussion upon

The Undesired and Unexpected Actions of Medicines, including Tolerance and Idiosyncrasy to, or Abnormal Results from, Ordinary Doses.

After a few introductory remarks, he said: Drugs may exert an unexpected action either (1) by failing to produce their usual effect, (2) by having an excessive effect, and (3) by having an unusual effect. In discussing the action of drugs we must always remember it is really the reaction between the drug and the organism which we are considering and an alteration in the effect may be either due to the drug or to the organism. It is necessary to insist upon the fact that we are apt in prescribing to be misled by names and to think that what we have administered to our patients under a certain name is always the same thing.[1] One of the saddest cases of this is that of Mr Myer of Winschotén, Holland, who prescribed aconitine for a patient in what he thought to be a perfectly safe dose, and as the patient complained of the effects he took double the dose of it himself with the result that he died from it in five hours. Nor was this fatal result much to be wondered at because pure aconitine is 300 or 400 times as strong as the old German preparation. Such extreme cases are fortunately rare, but I believe it is by no means infrequent that cascara sagrada fails to produce its effect because the bark has been secured from the wrong species of rhamnus. But even when procured from the same plant tinctures and other preparations may differ very much in strength according to the place where the plant is grown and its age, especially as to whether it is flowering or not. Moreover, many plants contain more active principles than one and sometimes these active principles are antagonistic to one another. Another source of error is that plants may have deteriorated by keeping in the druggist's shop and so lost their original virtues. In the hands of the purchaser they may have changed their strength or action. I remember reading the case of a child who was said to have died from one drop of laudanum, but this laudanum had been kept on a mantleshelf for a considerable time and the mouth of the bottle only stopped by a twisted piece of paper so that the original tincture of opium had become converted into a strong liquid extract by evaporation. Badly preserved solutions of morphine appear sometimes to undergo change with the formation of apomorphine or some other product which gives rise to vomiting. Occasionally the very purity of drugs may alter their effect for the worse. It was first pointed out by Dr Leech whose early death everyone who knew him deeply deplores, that artificial salicylate of soda owes its inferiority to natural salicylate not to the presence of any impurity but really to the absence of a certain amount of salicylate of methyl which exists in the natural product. Some time ago when prescribing nitrate of potash with the view of lessening high arterial tension and arresting epistaxis I found that the patient was immediately relieved by the use of saltpetre which he got from an oil shop On having the prescription made up at a chemist's with pure nitrate of potash the epistaxis began again. When he told me this I suspected that the ordinary nitrate contained a small amount of nitrite and on adding about half a grain or a grain of nitrite of soda to the 15 or 20 grains of nitrate of potash that he had been taking the epistaxis again ceased immediately This result explained to me the observation made by a very old medical man who told me that although he belonged to a very gouty family he kept away gout by taking 20 grains of nitrate of carbonate along with bicarbonate of potash and the nitre that he got from a gunmaker was always better than what he got from a chemist, the small amount of nitrite tending to keep down the high tension which his gouty kidneys would otherwise have produced.

---

[1] Kunkel. Toxikologie, p. 768.

[Sir Lauder Brunton here referred to the presence of impurities in bismuth and continued —]

Alterations in the effect of drugs may depend very much upon changes in them after they have been actually swallowed. In persons who live upon a vegetable diet and are accustomed to take but little salt, calomel appears only to have a slight action but in people who take a lot of salt or are accustomed to live upon salt provisions, a larger quantity of the calomel taken is converted into corrosive sublimate and thus the medicine may have an unexpectedly violent action An unusual amount of hydrochloric acid in the stomach may produce a like result, and this is a point to be borne in mind because nitrohydrochloric acid and calomel are both favourite remedies in conditions of biliousness

[After mentioning the effect of alkalies on antimony and upon resinous drugs Sir Lauder Brunton continued —]

Perhaps I cannot do better in introducing this subject than take a typical drug like arsenic and consider its different actions and afterwards compare them with those produced by other drugs. A drug may act on the body at the point of application whether it be skin subcutaneous tissue, raw wound or mucous membrane. After its absorption it may act upon any organ of the body to which it is carried by the blood. It may act during its elimination upon the same parts on which it usually acts during its absorption—namely the skin and mucous membranes as well as by the one great eliminating organ—namely the kidneys. The action of any drug whilst circulating in the body depends to a great extent on the amount present in the blood and this amount is determined by the difference between the quantity absorbed and the quantity excreted in a given time If absorption be rapid and excretion slow much of the product will circulate, whereas if absorption be slow and excretion rapid very little will be present in the blood at any one time. A drug may act at one time more violently upon the point of application at another on the organ to which it is carried by the blood and yet another on the organs of elimination. A large dose of arsenic taken by the stomach will irritate that organ and may be ejected by vomiting without being absorbed to any extent thus leaving untouched the organs generally as well as the channels of elimination. John Hunter and Sir Benjamin Brodie showed that when arsenic was applied to a wound it was absorbed with rapidity and was eliminated very rapidly by the mucous membrane of the stomach so much so that it produced inflammation of the stomach before any appearance of inflammation showed itself in the wound. But arsenic has long been used as a secret remedy in cases of cancer and often it causes the part to slough away without having any general action, although every now and again cases of poisoning have occurred The chief rule for avoiding any poisonous action in such cases is said to be by using the arsenic paste very strong and over a small area. If used in too dilute a form it is absorbed but if used very strong it forms a local slough and is not absorbed at all. In the poisoning by beer in Manchester so much was diluted that it appeared to have little local action when drunk but after absorption it was carried to the mucous membrane of the stomach and intestines and during its elimination by these organs gave rise to sickness and diarrhœa. During its elimination also by the skin it produced many cutaneous eruptions and while circulating in the blood gave rise to neuritis anæmia, fatty degeneration of the liver muscles and heart with muscular weakness loss of sensibility great pain and a tendency to syncope. In the case of poisoning by arsenic in beer the drug was taken in small quantity at a time and in a state of dilution that prevented its local action on the intestinal canal, but its ingestion was so continuous that the eliminating organs could not get rid of it as quickly as it was absorbed and so it accumulated in the organism. Exactly the reverse occurs in the arsenic eaters of Styria. These people take a somewhat large dose at once but they take it in a dry form so that it shall not be absorbed too quickly and the eliminating organs pass it out of the body with sufficient rapidity to prevent poisoning It is highly probable that a small quantity may circulate in the blood for a long time before the least traces of it are eliminated Styrian arsenic eaters take their doses at comparatively long intervals generally a week or a fortnight but very minute doses regularly taken are said to have the same effect in producing plumpness and strength and in some girls boarding schools in Switzerland arsenic is said to be regularly put in the food for the purpose of improving the girls' appearance

[Concerning tolerance Sir Lauder Brunton said —]

If we consider what the condition of a cell will be when a new substance is brought by the blood we may form a hypothesis regarding the tolerance which even if imperfect may help us to understand the nature of the phenomenon New substances will come first of all in contact with the outer part of the cell so that the relationship of the exterior to the interior will become altered gradually the new substance will penetrate through the cell and unless fresh quantities of the new substance be carried to the blood the cell may go on almost unchanged in its functional activity Even if new quantities are supplied to the exterior of the cell a large proportion of substances will be required to produce the same relative change than at first and so it will gradually lose its primitive effect larger and larger doses being constantly required until at last they seem to have almost no action This hypothesis will help us to understand the gradual loss of effect both of purgatives and narcotics but we must remember that complete imbibition of a cell with a new substance may alter its whole activity although the relationships of the different parts of the cell to one another are undisturbed In this way the arsenic may tend to cause fatty degeneration and atrophy of various cells both muscular and nervous, and to produce a series of changes which though very slow may surely lead to a fatal result In the case of arsenic the cumulative action which was so well observed in the Manchester epidemic was due to the constant ingestion of larger quantities than the eliminating organs could remove and the same is the case with mercury and lead and the sudden appearance of mercurial or lead poisoning is only caused by the accumulated amount becoming at length sufficient to produce it. In the same way the curious greenish purple of the skin produced by the long-continued use of nitrate of silver occurs after long accumulation and in the case of this metal it is stated that this undesirable result may follow the use of a small amount of silver if it has been freely administered years before little or no elimination having occurred in the interval. In the case of two drugs especially —digitalis and strychnine—sudden development of poisonous symptoms has been specially noted. In some cases it is possible that this may have been due to a cumulation of the active principle in the intestinal canal with sudden solution and absorption in consequence of some article of food or drink having been taken in the same way as I have already spoken in regard to quinine but generally I believe it is due to those drugs causing a lessened flow of urine and thus arresting their own excretion.

Sir Lauder Brunton then passed to consider the aromatic series nearly every member of which has a tendency more or less to produce cutaneous eruptions with feebleness of the circulation with sometimes a tendency to collapse and with a tendency also to anæmia when administered for a long time."

[Examples were then given of drugs belonging to this series and other drugs which produce cutaneous eruption and heart failure With regard to salicylates Sir Lauder Brunton continued —]

For some time past I have used a method of treatment in-appendicitis which has given very satisfactory results It consists of administering salicylate of soda and belladonna in very full doses. I usually prescribe 15 or 20 grains of salicylate every two hours and 10 or 15 minims of the new tincture of belladonna. The drugs may either be given at the same time or in alternate hours, but they are not mixed because each drug should be taken until the first symptoms of its physiological action appear, singing in the ears in the case of salicylate, and dryness of the mouth, dilatation of the pupil and quickness of the pulse in the case of belladonna When these symptoms appear the drug is either to be stopped entirely or greatly diminished in quantity In two cases the patient has become delirious before any dryness of the mouth or other symptom of physiological action of the belladonna appeared, but in both cases I found that a tendency to insanity was present in the family Both patients had been perfectly sane all their lives, but the belladonna appeared to develop the latent tendency for the time being

[Sir Lauder Brunton concluded his interesting address by some remarks on narcotics]

INDUSTRIAL HYGIENE AND DISEASES OF OCCUPATION

Wednesday, July 30th.

The **President** of the Section (Dr B Arthur Whitelegge) opened the proceedings by delivering a short address in which he referred to the fact that they met on the centenary of the first Factory Act and in the first year of an important consolidating and extending Factory Act In the course of his remarks he pointed out that factories and workshops had been built and the plans had been passed by the responsible authorities without due consideration of ventilation or of sanitary accommodation or means of escape in case of fire , the remedy later on was usually more costly and less effective than proper provision at first would have been So, too, with machinery, which was too often ordered, made, and taken into use without consideration of the dangerous points to be guarded or avoided, however obvious they might be , and that occurred in the case of machinery which, when made up for export to other countries, was sent out guarded as it should be. So, too, with the fans which were intended to carry away dust or fumes , the exhaust was often taken not from the point which common sense would dictate—namely, the place of origin of the mischief—but from some remote part, so that the impurities had to be diffused through the air to be breathed before they could escape

Dr S **King Alcock** was then called upon to open a discussion on

The Value of Systematic Medical Examination of Workers in Dangerous Trades

The point he wished to emphasise was that the nature rather than the severity of the symptoms should be their guide in classifying any case of trade poisoning , a slight attack of optic neuritis was a more impressive danger signal than was the severest case of uncomplicated colic The physical signs and symptoms present in any case of poisoning might of course have their origin in other diseases the possible existence of which should be investigated if present Although each symptom considered separately might have a doubtful significance the concurrence of two or more led well nigh to certainty when each had some separate pathognomonic importance. It was the conjunction of colic with wrist-drop, of optic neuritis with a blue line, of anæmia with paresis, that enabled them to diagnose lead poisoning, whereas the unassociated presence of any one of these symptoms would always leave room for doubt.

A paper was then communicated from Mr B M **Bond** (Poole) who considered that the chief value of the examination in dangerous trades lay in the power possessed by the surgeon to suspend or to discharge workers injuriously affected by their work.

Mr W H. **Vickery** (Newcastle upon-Tyne) sent a paper in which he put forward the view that every worker in lead, no matter how careful, absorbed a certain amount He urged that it was the duty of the inspecting surgeon to try to determine at what point absorption passed the boundary line of safety so that he might suspend the worker and prevent the onset of an attack of lead poisoning

Dr W A. **Atkinson** thought that the periodical examination of lead workers was undoubtedly a safeguard against plumbism, because there was an opportunity of detecting some of the earlier symptoms and such cases if taken away from the influence of lead and properly treated seldom developed the more marked symptoms of lead poisoning

After Dr J **Holmes** and Dr T F **Young** had spoken,

Dr T **Oliver** (Newcastle upon-Tyne) contributed a paper on the subject under discussion. He said that the utility of the examination was based upon experience. Nearly all civilised countries had legislated to a greater or less extent for workers in white lead, mercury, and phosphorus By thus acting the various Governments had recognised that ill health followed unregulated employment in trades, while the compulsory medical examination required by many in addition showed that it was recognised that by timely detection much of the evil consequences of industrial poisoning could be prevented.

An interesting and important paper on the Injurious Influence of Fast Aniline Black Dyeing Processes was then read by Mr W F Dearden (Manchester)

THE ANNUAL MUSEUM.

There was but little attempt to make the exhibition this year as socially attractive as was the preceding one at Cheltenham , indeed, any such attempt would probably have been attended with limited success, since a strictly rectangular hall was the only available building for the purpose, whereas the Winter Garden in Cheltenham afforded every opportunity of making the annual museum attractive and artistic The Winter Garden proved a pleasant lounge and retreat and was, besides, approached by beautifully kept lawns The Drill Hall in Burlington street, Manchester, is situated in a somewhat unpleasant neighbourhood not very far from the Owens College and both places could hardly be said to be within easy distance of the leading hotel quarters The opening ceremony on Monday was featureless Dr Woodcock briefly introduced the Lord Mayor of Manchester, who declared in equally brief terms the exhibition to be open A reception of visitors then took place and the attendance was fairly good. Despite the heavy showers on Tuesday there was a satisfactory influx of medical men, and the interest taken in the exhibits was evidently brisk

Electrical appliances and photo therapeutic apparatus perhaps attracted most interest, although considerable attention was given to the excellent surgical and sanitary appliances displayed, as well as to new forms of drugs, new pharmaceutical preparations, and so on There was a small motor car and carriage section. As might have been anticipated many well known local firms were represented. It may be remarked that there was a decidedly diminished tendency to worry the visitor to give his attention to any particular exhibit, and there was an absence of that kind of objectionable solicitation which borders so closely upon mere touting It is evidently realised that medical men know best what interests them most, and it would add considerably to their comfort if the unasked for and generally exaggerated statements made by the exhibitors could be suppressed altogether Of course, the exhibitor generally possesses some special knowledge of his exhibits, but there is no necessity for him to give the medical visitor any information unless requested to do so To be persistently hailed on all sides with "Have you seen this, Doctor?" "May I draw your attention to that, Doctor?" "Will you put your name in my book?" and so on, is annoying and calculated to defeat the real and excellent aim of the exhibition—i e to introduce to the notice of the practitioner any pharmacological advances or other improvements

Adhering to our practice in previous years, we propose to review what we consider to be the more important exhibits, which for convenience may be classified as follows I. Drugs , II Foods and Food Products , III Sanitary Appliances, Disinfectants, &c. , IV Surgical Instruments and Appliances , V Mineral Waters, Beverages, &c. , VI Publications , and VII Miscellaneous

I.—DRUGS

In touch with so many busy industrial centres it might have been expected that Manchester would afford abundant opportunity for exhibiting a great variety of drugs. And such was the case. The midland towns were well represented With regard to drugs and their preparations there was no striking advance to report, and certainly no particularly important departure relating to the forms of administration appears to have taken place. Attention is of course still being directed to the improvement of pills tablets, cachets bases excipients and so forth an attention which has contributed so much towards pharmaceutical elegance and to bringing dosage to a remarkable pitch of accuracy Amongst the local firms represented were Messrs. James Woolley Sons and Co Limited, who offered an admirable selection of new therapeutic agents for inspection Amongst these were argonin duotal purgatin, urosin, and other drugs which have been described already in our analytical *columns. Mention should also be made of* akolethe a solution of the sedative principles of opium Again, cancellous tissue described as decalcified bone, has been suggested as an absorbent dressing for use in the treatment of granulating wounds fistulas and ulcers Amongst the elixirs shown was elixir terpini co each fluid drachm containing one grain of terpin hydrate and $\frac{1}{16}$th grain of heroin hydrochloride it is useful in the irritable conditions of the respiratory tract. Lastly a special preparation is unguentum resorsol an ointment prepared with resorcin tar, zinc, and bismuth for use in inflammatory conditions of the skin. Messrs. Charles Midgley, Limited of 23 St. Ann s-square, Manchester presented to view a number of interesting preparations, the feature of the exhibit, however being an excellent series of medicated soaps. Amongst the soaps prepared both with an alkaline and a superfatted base are ichthyol, sulphur and white birch tar soaps. The superfatted soaps include also nicotine soap and resorcin soap and *others The same firm prepare* a series of medicated pastilles and special liquores Amongst the former may be mentioned eucalyptus and codein pastilles and the dionine lozenge and amongst the liquores may be *noted those containing papain pepsin santal and copaiba.* These liquors are designed for the use of practitioners who do their own dispensing Mr J C Arnfield of 7 and 9 Lower Hillgate, Stockport, exhibited a number of useful preparations amongst the most novel of which were Unna s pastes and hæmorrhoidal jellies in collapsible tubes and eye ointments contained in gelatin capsules. By merely piercing the capsule the desired quantity of ointment may be easily obtained. Colloiderm may be mentioned as an excellent aseptic collodion evaporating rapidly Messrs. R. Sumner and Co of 50A Lord-street Liverpool, exhibited a number of preparations illustrating chiefly improved methods of administration such as gelatin perles and capsules and gelatin coated pills free from pin holes. Antisepticine is also worthy of mention being a non poisonous antiseptic containing the active agents thymol, eucalyptol peppermint, gaultheria and *benzoic or boric acids* Antisepticine is suggested for internal use in flatulence as an anti fermentative and in dysentery and diarrhœa. An emulsified chloroform is also prepared by this firm, it is convenient in enabling the extemporaneous preparation of acqua chloroformi B P The Bayer Co. Limited of 20 Booth street, Manchester exhibited their well known preparations. Amongst these are agurin " a theo-bromine compound possessing diuretic properties, the silver proteid protargol aspirin, a substitute for the salicylates and hedonal, a hypnotic of the urethane group A well arranged stall replete with a great variety of preparations was that of Messrs. Wyleys Limited of Coventry The exhibits included ichthyol pessaries and suppositories *throat* and other pastilles, and standardised tinctures and medicines in capsules coated pills, cachets and pellets. Messrs. Duncan Flockhart and Co of 104 South Canongate Edinburgh, exhibited the well known preparations connected with their name, the chief of which is, of course, specially pure chloroform, but other preparations were included such as gelatin capsules, tablets, and infusions. Coming to London firms, Mr W Martindale of 10 New Cavendish-street London W exhibited a number of preparations well worth attention. Amongst these were sterules " or sterilised eye-drops contained in capillary tubes (the method is convenient and effective) compressed moss a good absorbent dressing sodio magnesian aperient with caffeine and many other useful preparations. The portable urine test and bacteriological test apparatus are well known on account of their special usefulness. We have already described in our analytical columns Dolles s aromatic iron milk, for which the British Iron Milk Syndicate Limited, of 115 and 116 Strand London W C. are *the agents. It is* an ingenious preparation of pyrophosphate of iron suspended in water with the aid of glycerine. The iron salt is unchanged until it reaches the beginning of the intestinal tract where it is absorbed. It is without the usually unpleasant effects of iron salts and is not astringent, while it is agreeable to take. Messrs C J Howlett and Son, of 35, Charlotte-street, London, E.C exhibited a number of improved pharmaceutical *preparations* including several valuable mistura, besides many comparatively new remedies including urea and the cacodylates. Amongst the antiseptic preparations were a cream a jelly and a liquid ether soap An interesting variety of preparations, medical and antiseptic, was *presented to view on the stall of Messrs.* Corbyn Stacey and Co Limited, of 300 High Holborn, London. Antiseptoform is a wax like solid which gives off formaldehyde gradually at ordinary temperatures while on heating it generates the same gas in large quantities It is therefore useful for aerial disinfection. The exhibit included a number of elegant extracts, liquors and syrups. Mr Frank A. Rogers of 327 Oxford-street London W exhibited several forms of apparatus for producing sprays for medical application well adapted for laryngeal work post nasal work, and in the treatment by spray of other cavities. An interesting series of medicated ointments in the form of cylindrical sticks known as hypodermules was also worthy of attention. We have already noticed some of the more important preparations of the Anglo-American and Continental Pharmaceutical Company of 39A Tamworth road, Croydon. These include Huxley s compound syrup of the acid glycero-phosphates and an antiseptic plasma dressing and dusting *powder* The small spherical capsules known as kugloids may be mentioned they contain glycero phosphate of quinine, benzoate of creasote, and eucalypto, the therapeutic indications being obvious Messrs Burgoyne Burbidges, and Co of 12 and 16 Coleman street London, E C exhibited a number of new silver preparations useful in the antiseptic treatment of wounds Amongst them were actol credé (lactate of silver) antiseptic credé *(citrate of silver) collargolum (colloidal silver credé)* and unguentum credé (colloidal silver ointment) Acoin the comparatively new local anæsthetic for surgical ophthalmological and dental operations has already been described in our analytical columns. An interesting collection of synthetics generally of a beautiful crystalline character was tastefully arranged on the stall of Messrs. Zimmer and Co of 33 Lime-street London, E.C. These included euquinine so-called tasteless quinine said to possess the same antipyretic action as quinine, the dose being the same, urosine and dymal, the basis of an antiseptic dressing The Angier Chemical Company of 32 Snow hill London E C exhibited preparations of their *emulsion of petroleum with hypophosphites. It is described* as acting as a demulcent and sedative throughout the intestinal tract Maltine serves as a substitute for ordinary syrup for the exhibition of iron and the phosphates with the added advantage that it possesses diastasic properties. The Maltine Manufacturing Co of 24 and 25 Hart-street Bloomsbury exhibited a number of preparations of the nature indicated compounds were also shown of maltine with *cod liver oil cascara, &c.* Messrs Parke, Davis, and Co of 111, Queen Victoria street, London E.C exhibited a very large choice of preparations including special drugs, serums and toxins antiseptics and chocolate-coated tablets Special emphasis was laid upon the value of adrenalin the active principle of the suprarenal gland as an astringent hæmostatic and vasomotor stimulant. The exhibit included the nuclein compounds of mercury silver iron, and copper The Charles H Phillips Chemical Co of 14 Henrietta street, Covent-garden London W C exhibited an elegant preparation of magnesia it consists of a uniform emulsion of the pure hydrated oxide of magnesium and contains 24 grains in each fluid ounce. It has the advantage of acting as an antacid in dyspepsia without the production of carbonic acid gas It serves as an excellent mouthwash and is described as of peculiar value in the colic of *infants. Messrs Oppenheimer* Son, and Co. of 179 Queen Victoria street, E.C. had a well-arranged stall on which their palatinoids and bi palatinoids figured for the most part. The palatinoids of tinctures and the bi palatinoids of compound syrups are worthy of special mention An excellent variety of medicine cases suitable for many purposes was also shown. These included emergency cases pocket medicine cases and a combined *emergency and midwifery case* The Peptenzyme Co. of 80 Gloucester road South

Kensington, London, S W , besides exhibiting peptenzyme tablets and elixir, preparations which we have had occasion to report upon in our columns, showed also a preparation called "trophonine," which is described as a palatable and highly nutritious liquid food, being derived from vegetable and animal proteids associated with the digestive enzymes , Another preparation worthy of note on this stall was "zymocide," a solution of several aromatic antiseptics Being non poisonous it is suitable for internal use as an anti-fermentative and in dysentery and diarrhœa. The chief subject of exhibit on the stall of Mr B Kühn of 36, St Mary at-Hill, London, was chinosol, which has the advantage of possessing not only strong antiseptic power, but a deodorising power also It occurs in the form of pure powder for medical use and in a crude form for common disinfectant purposes Tablets are prepared containing a definite amount of chinosol which enables the quick preparation of a standard solution The exhibit included a group of pharmaceutical preparations manufactured by Messrs Knoll and Co Of these we have already mentioned the interesting synthetic and purgative purgatin, in powder and tablets, and triferrin, a paranucleinate of iron This firm also showed graduated glass tubes containing ethyl chloride for inhalation in general anæsthesia. Messrs Arthur & Co , of 69, Berners street, London, W , made a special feature of their gold preparations known as bromaurum and hydraurum, said to be useful in the treatment of neurasthenia, epilepsy, and chronic rheumatism Samples of uric acid illustrating abnormal pigmentation caused by nervous degeneration and the action of bromaurum in obviating this pigmentation were exhibited. The exhibit included antiseptic handkerchiefs and aquaform, a local application for the relief of perspiring hands Of comparatively recent introduction is the interesting substance ovo lecithin, consisting of the three lecithins of stearic, oleic, and palmitic acids contained in the yelk of the egg Mr Billon, of 16, Water lane, Great Tower street, London, E C , prepares pills of ovo lecithin and a special confection for children, and fluid ovo lecithin for intra muscular injection

ASYLUM REPORTS

East Sussex County Asylum (Annual Report for 1901) —The average number of patients resident during the year was 956, comprising 406 males and 550 females The admissions during the year amounted to 222—viz , 120 males and 122 females Of these 181 were first admissions Dr E. B C Walker, the medical superintendent, states in his report that among the admissions there were 75 males and 70 females whose prospect of recovery was bad or hopeless , 35 males and 38 females were found to be actively suicidal on admission The number of patients discharged as recovered during the year amounted to 74—viz , 34 males and 40 females, or 7 7 per cent of the average number resident. The deaths during the year amounted to 90—viz , 45 males and 45 females or 9 4 per cent , as calculated on the same basis Of the deaths three were due to pulmonary, or other forms of, tuberculosis six to cerebral atrophy, six to cardiac disease, seven to nephritis, nine each to epilepsy and senile decay, 14 to pneumonia, 18 to general paralysis of the insane and the rest to other causes One female patient was admitted while pregnant and was confined of a child four months afterwards. She was subsequently discharged as recovered Four patients escaped from the asylum but three of them were brought back. During the months of April, May, June, and August one female and 14 male patients were attacked with measles, the disease being introduced from the neighbourhood, where it was very prevalent Early in the year the accommodation for male patients was found to be inadequate To make provision for them a contract was entered into with the Nottingham City Asylum for the reception of 30 males In April beer as part of the ordinary diet of patients was discontinued , it caused but slight discontent on the part of a few patients, and the addition to the dietary of more cheese cake, and jam was found to be much appreciated. The Commissioners in Lunacy state in their report that the asylum as a whole was in good order, that 58 per cent of the males and 68 per cent. of the females were usefully employed, and that the medical case books were well kept. The committee of management states in its report that during the year the attendants' and nurses' leave has been increased and the diet scale improved No cows are now purchased for the farm without undergoing the tuberculin test

Obituary.

JOHN PERMEWAN, L R.C.P EDIN

MR. JOHN PERMEWAN died at his residence, Redruth, Cornwall, on July 26th in his seventy first year The deceased, who received his medical education at St. Bartholomew's Hospital, had resided for many years in Redruth where he had with his eldest son, Dr A E Permewan, J P , an extensive practice Mr Permewan was attending to his professional duties to within a fortnight of his death which was caused by pneumonia following a chill The deceased will be greatly missed in Redruth where he took a great interest in all local matters and was one of the originators of the West Cornwall Women's Hospital. Mr Permewan also erected at his own expense seats for the convenience of invalids in various directions in the outskirts of Redruth The deceased leaves two sons, both of whom are members of the medical profession, and two daughters His wife, who was also greatly esteemed at Redruth, died about three years ago

DEATHS OF EMINENT FOREIGN MEDICAL MEN —The deaths of the following eminent foreign medical men are announced —Dr Karl Marinus Reiss, Professor of Pathology in the University of Copenhagen, at the age of 73 years The scientific papers published by him chiefly related to diseases of the respiratory organs —Dr Matias Nieto of Serrano, Marquis de Guadalerzas permanent President of the Royal Academy of Medicine of Madrid

Scott of Hayward's Heath £5000 are bequeathed to the Sussex County Hospital and £3000 to the Royal Hospital for Consumption, Ventnor —By the will of Mr James Hancock of Sheffield £500 will ultimately go to the Jessop Hospital for Women.—By the will of Mr A. Scrutton of Woodford £500 are bequeathed to the London Hospital for the endowment of a bed and £500 to Mrs. Mearnes's Convalescent Home at Folkestone for the same purpose —The Duke and Duchess of Aosta have sent a donation of 1000 francs to the funds of the Italian Hospital, Queen square.—The City Corporation has granted 50 guineas towards the fund for building a nurses' home for the British Lying-in Hospital, Endell street, and the same amount to Queen Charlotte's Lying-in Hospital, Marylebone road —By the will of Mr Thomas Patey Chappell £500 are bequeathed to St. George's Hospital and £100 to the Teddington Cottage Hospital.—Miss Clara Squire by her will bequeathed £100 each to the Charing Cross Hospital, the Cancer Hospital, Fulham, the Middlesex Hospital, St Mary's Hospital, Paddington, and the National Hospital for the Paralysed and Epileptic, Queen square, and £200 to the Westminster General Dispensary, Soho

INCREASE OF SALARY —At the meeting of the Plympton Rural District Council held on July 25th it was unanimously decided to increase the salary of the medical officer of health (Mr S Noy Scott, L R.C P Lond , M R.C S Eng , D P H.) from £150 to £200 per annum

HOSPITAL FOR CONSUMPTION, BROMPTON —A country branch and convalescent home for open air treatment in connexion with the Hospital for Consumption, Brompton, is now being built at Heatherside from plans prepared by Mr E T Hall, F R.I B A. This building has been specially designed and will combine the latest improvements The patients will be drafted from the parent hospital on the recommendation of the physicians in charge. The site is on the well known Chobham Ridges, about three miles from Frimley, Surrey This new departure will involve a large outlay, about £60,000, and funds are urgently needed.

MAUD HOSPITAL, EXMOUTH —The second annual meeting of the subscribers of this institution was held on July 22nd , the report showed that 73 in patients and 104 out-patients had been treated during the year ended June 30th, 1902. The financial statement showed that the income amounted to £527 and the expenditure was £455 At the last meeting of the subscribers of this hospital it was decided that a new institution should be erected under the name of "The Exmouth Cottage Hospital" as a memorial to the late Mrs Hume Long The cost is estimated at £4000, towards which £3000 have been received and the committee hope that the new building will be completed within the year

Parliamentary Intelligence.

HOUSE OF COMMONS

TUESDAY JULY 22ND

The Sanitary Condition of Post Offices

SIR WALTER FOSTER asked the Secretary to the Treasury as representing the Postmaster General whether the Post Office had arranged to permit the inspection of post-office buildings by Factory Act officials when such inspection was considered necessary and whether the Postmaster General would direct that upon the staff making complaints in writing with reference to the sanitary condition of the buildings in which they work an inspection would take place and the result be communicated to the men concerned.—Mr AUSTEN CHAMBERLAIN replied The Postmaster General has made an arrangement with the Home Office under which he is able if he considers it necessary to avail himself of the services of a factory inspector in dealing with any question whether a post-office building fulfils the conditions of the Factory Acts, and he has already done so Every complaint made by the staff as to the sanitary condition of a post office building is thoroughly investigated but the Postmaster General cannot undertake to call in a factory inspector every time a complaint is made.

WEDNESDAY JULY 23RD

Medical Examination of Passengers at Calcutta

Mr WEIR asked the Secretary of State for India whether any arrangements had yet been made for the punctual attendance of the medical officer for the examination of passengers leaving Calcutta by morning sailings of outward bound steamers and could he state whether the shed in which passengers were examined had yet been put in a state of repair and the practice of medical examination in a public thoroughfare discontinued —Lord GEORGE HAMILTON replied I have no information about these matters They are such as are dealt with by the local authorities without being reported to the Secretary of State Any complaints on the subject should be addressed to these authorities

THURSDAY JULY 24TH.

Poor-law Reform in Scotland

On the motion of Mr Baird a Bill was introduced and formally read a first time to extend the powers of the Local Government Board for Scotland in regard to the detention of poor persons in poor houses and parish hospitals

Poor law Medical Officers and Private Practice.

Mr CATHCART WASON asked the Lord Advocate if his attention had been called to an advertisement for a Poor law medical officer for the parish of Farr Sutherlandshire and whether such advertisement was in accord with the regulations of the Local Government Board —The LORD ADVOCATE replied: The attention of the Local Government Board has been called to the advertisement referred to and it is in communication with the parish council of Farr The Board has not made a formal regulation on the subject, but when it finds a parish council interfering with the fees charged by its medical officer in his private practice it calls upon the council to cease doing so, and it has repeatedly taken this course

Dental Provision at the Duke of York s School

Mr CATHCART WASON asked the Financial Secretary to the War Office if any arrangements had been made for dentistry and dental inspection of the children at the Duke of York s School and, if so would he state their nature.—Lord STANLEY replied: Arrangements have been approved for the provision of a dentist and the necessary materials for dentistry for the next 12 months after which period the arrangements are subject to revision

Future address Auckland New Zealand

N.B —A fee of 5s is charged for the insertion of Notices of Births Marriages and Deaths

Notes, Short Comments, and Answers to Correspondents.

RELIGION AND QUACKERY

A ROMAN Catholic newspaper makes the following extraordinary comments upon the letter signed E J H" which appeared in the columns of THE LANCET of July 19th (page 194)

Medicinal Controversy —THE LANCET has opened its columns to a correspondent. E J H who, to judge from his sympathies, is also a medicine man This E J H' is indignant that the monks of Buckhurst Abbey should advertise their salve suggesting that for reprisals sake some members of the medical profession should announce that they will be prepared to 'preach hear confessions and perform some of the other functions peculiar to the clergy' Can t 'E J H see he is doing the first albeit, badly whilst the body we take it he represents is not unaccustomed to hear confessions in quite another form The editorial comment is quite juridical, and apparently without prejudice

A Matter of Discretion —But there are very many persons who trust simple remedies rather that the complex and unknown qualities of the medicines used by the modern disciples of Galen and Hippocrates to say nothing of Æsculapius Given this fact we would ask the editor of THE LANCET, Is it not better that the preparation of these simple remedies should be in the hands of trusty monks than as sometimes happens in those of men of little skill and less stability of character? The question of the propriety of advertising the remedies is quite out of THE LANCET editor's range, and when approval is given by Catholic authorities we would advise the physician to stick to his pharmacopœia, and mind his own patients

As the editor of our contemporary has asked us the question we have no hesitation in saying that it is not better that the preparation of any remedies should be in the hands of monks, for monks in their corporate capacity are not chemists pharmacologists, or medical men A trusty" monk is one who discharges his monastic duties with conscientiousness not one who makes salves Lord Kitchener is a 'trusty" soldier and Mr Victor Trumper is a trusty" cricketer but neither gentleman ought to be allowed to manufacture and to traffic in medicinal nostrums because neither has received the necessary training We think that we know our own range but we are certain that the editor who questions this matter is not in an equally good plight he does not understand the evils of quackery the qualifications of professional medical men or the limitations of professional pietists He is apparently unaware that the duties to the community discharged by the monks in the middle ages have now devolved on other people all the education of the country being no longer centred in the Church THE LANCET by the way, is not concerned with differences of religious opinions and we need hardly say that our feelings would be just as much against a confraternity of the English Church making and selling medicinal remedies as it is against similar action on the part of a Roman Catholic body frequent evidence of this impartiality will be found in our columns

FUND FOR MEMORIAL TO LATE SURGEON GENERAL NASH

THE following additional subscriptions have been received —

	£	s	d		£	s	d
Surgeon General J B C Reade C B K H S	1	0	0	Previously acknowledged	111	1	0
Lieutenant Colonel L E Anderson	1	0	0	Total	114	1	0
Surgeon Major General J Davis	1	0	0				

'A NOVEL PATENT"

UNDER this heading in THE LANCET of May 17th 1902 page 1434, we drew attention to a patent burial vault" consisting of a kind of outer coffin having a groove or channel all round the upper margin of the main portion or body, to contain a sealing material while the lid has a flange which dips into the sealing material We understand that Dr L G Thompson some 14 years ago while he was surgeon superintendent of Launceston Hospital Tasmania designed a similar metal shell having a lid fitting into a water joint The shell had a glass window in it so that a body could be viewed.

THE 'Y FUND

SURGEON GENERAL H S MUIR begs thankfully to acknowledge additional donations towards the above Fund from Lieutenant Colonel J W L Macnamara I M S and the following officers of the Royal Army Medical Corps —Colonel J Dallas Edge, C B Lieutenant-Colonels J Lees Hall W J Baker J A Gormley, T J O Donnell D S O C W Thiele G E Twiss and E. Butt, Majors W W Pike D S O C Birt F R Nowland T B Beach, H T Knaggs Reilly and T Du B Whaite Captains C E Pollock H. B G Walton, G B Crisp D D Shanahan G W Tate J Hennessy J C Jameson, G St C Thom Chevers C G Spencer and J H. Rivers Lieutenants W L. Steele H Richardson R. F M. Fawcett, J V Roche, J J W Prescott D S O and H Bransbury and Lieutenants and Quartermasters Spackman and Morrison The fund now amounts to £483 It may be explained that this is in response to an appeal made privately to members of the profession for benevolent aid in a distressing case which has been described in a letter sent to a limited number of medical men (who would help the cause by kindly 'handing on' to *confrères*) Should any reader of THE LANCET desire further particulars with a view to expressing *practical sympathy*, a copy of the letter will be forwarded on application to Surgeon-General Muir, 26, Kensington-gardens terrace, Hyde Park, London, W

INCOME TAX AND CLUB APPOINTMENTS

WE have received the following letter for publication It is a copy of one sent to the Inland Revenue by a medical man holding a club appointment :—

Alderney House Alderney, C I
July 12th, 1902

SIR —The enclosed £2 4s 4d 1st quarter s moiety, 1902, I send under protest and intend to apply to the Income Tax Repayment Association with regard to this payment and two previous payments

The charge is in regard to profits from appointment as medical officer under the Shepton Mallet Board When I tell you that the appointment consists in taking charge and visiting at all hours of the day and night the sick and infirm of ten (10) parishes—viz , Ashwick, Oakhill, Binegar, Emboro Stratton-on the Fosse, Holcombe Stoke Lane Downhead West Cranmore, and East Cranmore, and supplying drugs and instruments, for £115 per annum (which includes keeping and attending three distant surgeries) you will wonder where the profit comes in The district extends from Chewton Mendip to Leigh on Mendip (12 miles) and from Chilcompton to Shepton Mallet (10 miles), one horse cannot work it

The Shepton Mallet Board, with a wealthy brewer at its head (I hope he pays income tax for all his public-houses) cuts the doctor down to 10s for a midwifery case and driving miles to examine and certify a lunatic is reduced from 21s to 10s When I attended a confinement I sometimes had to pay 12s for carriage hire and have gone nine miles in the snow in the middle of the night The entering and clerking of all the cases, correspondence &c., is worth employing a clerk for

Other unions pay for operations and fractures, Shepton Mallet does not (and it is a wealthy union) The reason I have troubled you with this statement is that for the last four years I have filled up forms and returned them in the usual way and found that after satisfying the assessor or collector at Emboro (Mr Flower) I had then to deal with the surveyor at Wells and after receiving assurances from him with regard to my position I have had to deal with the gentleman at Frome and finally found that Bath had joined in and that from all parts of the compass I was now being set upon to disgorge some of the 'profits"

If the same efforts had been directed against *higher game* what a fine income Oakhill would bring in After what I have told you with regard to No 2 (Ashwick and Oakhill) district Shepton Mallet Union you will not be surprised to know that about a dozen medical officers in as many years have moved across its horizon as in a cinematograph so to speak and that if the income tax goes on while the salary remains stationary the rate of the procession's progress will receive a still further stimulus

I was Sir, truly yours,
(Signed) J J HANLY, M A L R C P & S Ed,
Late Med Officer, Ashwick District.

The Secretary Inland Revenue, Somerset House

THE DIMINISHING POPULATION OF FRANCE

THE French people are threatened with a new danger An attempt is being made to obtain an alteration of the law to enable any citizen to obtain for the sum of one franc a "permit de chasse available for one day Amongst the numerous and brilliant accomplishments of the French shooting is not generally reckoned and the possibility that anyone may obtain a shooting licence for a franc has a serious aspect The gentleman who writes on Shooting in *Le Figaro* is fairly aghast at the danger as he feelingly observes, 'it would be impossible to walk in the country without the risk of being shot." The ordinary Briton looks with some misgiving on the present French sportsman but he, at any rate is a picturesque object when fully attired for the chase and it does not appear that he is as a rule, particularly destructive to any form of living creature, human or otherwise Should the franc sportsman come into being a new industry may be started in letting out to him a suitable 'habit de chasse" and a gun and we would commend the idea to M. Caran d Ache the first of living caricaturists His facile pencil would avail more than the strongest words we could pen to avert a danger which would undoubtedly tend to depopulate France

EAR DRUMS

THE A P Murray Company of Century House Regent-street W is issuing circulars curiously enough addressed 'To the Medical Profession, calling attention to the Murray' Invisible Ear Drum It is distributing a sample outfit of assorted drums for 17s 6d saying that 'the treatment of deafness is one which most physicians have overlooked, and yet it is a most lucrative one" Possibly that is why the A P Murray Company has stepped into the breach In the course of a pathological disquisition it is stated that head noises are caused by disorganised or disarranged ossicles and that the "Murray" Drum is not made of rubber because, no doubt, "Some people cannot wear a rubber coat or a mackintosh without causing an acute case of rheumatism." The company claims that it "offers a remedy which we believe has not and will not be equalled." If its remedy is as novel as is its pathology we at once present the company with a testimonial for we are certain that scientific medicine knows of nothing like it But what is the reason of sending this rubbish to medical men? Or have the circulars found their way also to the public?

THE LAW FUND

TRUSTEES: THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND THE MASTER OF THE SOCIETY OF APOTHECARIES OF LONDON

THE following additional subscriptions have been received by Dr Paramore, 2 Gordon-square W C and it will afford him much pleasure to receive as many more as possible within the next few days before the trustees have ceased to act —

◆

Mr C Hamilton Whiteford—The filthy little pamphlet is circulated in the most barefaced manner by the quack whose address is given within. We have referred to the matter and shown up the man in our columns. Of course to do so has not much practical result, as readers of THE LANCET are not likely to consult him What we are unable to understand is the powerlessness of both the police and the post-office to stop the dissemination of such obscenity The matter has been brought to their attention by us and others but no effective steps are taken

Surgeon—We think that the claim for payment in such circumstances is very seldom made, but the surgeon whose work has been done very often offers the fee to his professional colleague. This we think, should always be done whether the fee is accepted or not.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "To THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

---

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures, original articles and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES

THE INDEX TO THE LANCET

THE Index to Vol. I. of 1902, which was completed with the issue of June 28th, and the Title-page to the Volume, were given in THE LANCET of July 5th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1902 are now ready Bound in cloth gilt lettered, price 18*s*. carriage extra.

Cases for binding the half year's numbers are now ready Cloth, gilt lettered, price 2*s*. by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

Address in Obstetrics:

CARCINOMA IN WOMEN, CHIEFLY IN ITS CLINICAL ASPECTS.

Delivered at the Annual Meeting of the British Medical Association at Manchester July–August, 1902

BY WILLIAM JAPP SINCLAIR, M.D ABERD,
PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY IN THE OWENS COLLEGE, MANCHESTER.

Eadem orationis virtus atque angustii, sana et male affectis nos juvat, et bene habentes oblectat.—DEMOPHILUS.

INTRODUCTORY

GENTLEMEN,—Looking forward to standing in the position occupied once by such men of mark in their generation as Thomas Radford, Matthews Duncan, and Robert Barnes I am keenly alive to the fact that I do not owe the position, as they did, to a wide reputation and well-earned professional distinction. All the more, perhaps, having resolved to do the best I am capable of in the position, am I deeply grateful to the Council of this Association and to my too indulgent friends and neighbours whom chiefly I have to thank for the great honour conferred upon me.

In ruminating over the limited range of my intimate professional knowledge for a suitable theme for an address I had to keep in mind that the subject must be in the highest degree important in itself in order to be worthy of the occasion; it must be of wide interest in order to arrest the attention of those who are engaged in the practice of obstetric medicine in its widest sense and it must, if possible, be not a mere professional essay but have some important object and aim. I felt, also, that it would be an advantage to myself in preparing an address if I could discover a subject which had occupied my own thoughts in a special degree in the course of my practical professional work. With such conditions and many others essential to the most modest fulfilment of my task I felt that my undertaking was extremely formidable, but I knew that I could rely upon your forbearance and upon the intrinsic interest of my subject. I have chosen for the subject of my address Carcinoma in Women, chiefly in its Clinical Aspects, that is, very largely from the standpoint of the medical practitioner

Apology and justification.—It is generally believed that carcinoma of the sexual organs of women is as cancer occurring in men and to this extent, therefore, the subject is not one of obstetric medicine pure and simple. But malignant disease has a tendency to affect certain organs in women to an extent and with a relative frequency unknown in the other sex, and the clinical facts in the typical cases of cancer of the uterus make up a *tout ensemble*, an association of syndromata, a personality of the disease, that distinguish it from the malignant disease of any other organ. Then the frequency of its occurrence, the sex of its victims, and the pitiful character of its course from the social point of view lend it an interest and a pathos almost entirely its own.

If carcinoma of the uterus be the same disease as cancer in general, may not this individuality or personality of the malady make it the key to the situation? The frequency with which the disease occurs in a medical practice, the comparative similarity pervading the cases amidst individual differences, the facility with which operations can be performed and therapeutic agents employed, the possibility of careful clinical investigation and observation of cases in which the disease recurs and of cases immune from recurrence, are all circumstances which attract attention to this special form of malignant disease, render it a comparatively easy subject for inductive reasoning and therefore make of it perhaps the most promising field for clinical research.

Contrast between pathologists and clinical workers.—We must have observed a tendency to establish a contrast, or at least a certain degree of antithesis, betwixt clinical and scientific work. It was the devotion of the gifts of genius, of the highest intellectual endowments, to clinical investigation which lent dignity to the labours of former generations of physicians and surgeons and made their councils fruitful in conferring permanent benefits upon humanity Enlightened and patient industry and success in the observation and treatment of disease were the long and tedious, but the only sure, way to professional distinction and honour But now, since the advent of the modern developments of pathology, and especially of bacteriology, the unknown or misunderstood is accepted as magnificent by the whole medical profession, and a certain distinction can be achieved without much talent or industry, the microtome and the cultivation-tube—though work connected with them often resembles a sad mechanic exercise—have provided a royal road for many men into fields of clinical work which they have not known how to cultivate. They have shirked their apprenticeship to clinical medicine, yet they claim the consideration and emoluments due to the skilled and experienced journeyman.

But while I put in this word of protest against anything that may appear directly or indirectly to derogate from the dignity and from the appreciation of the usefulness of scientific clinical work I claim to hold in as high esteem and admiration as any man can the magnificent intellectual labours of the pioneers and masters of modern pathology and bacteriology Both clinicians and pathologists require all the mental endowments that Nature confers upon her most favoured in order to investigate the causes of disease and apply the remedies, and there is no room for formal or implied depreciation of the work of either Still we may institute comparisons.

Pathology and clinical gynæcology.—There is a general and a special aspect of the subject which we may examine in proportions suitable to the occasion (1) the investigation of the etiology and pathology of cancer in general, and (2) the consideration of cancer of the uterus in particular The practical gynæcologist may ask, What have investigations and researches into the etiology and pathology of cancer done for clinical gynæcology? The answer must be guarded at this stage at least. A late distinguished gynæcologist once said in his haste that a knowledge of anatomy was positively misleading with regard to the surgery of the pelvis. It can hardly be alleged that pathology has been misleading to the gynæcologist, for he has never trusted to its guidance. Men are wiser than their creeds they hold pious opinions in religion which, fortunately they never put into practice. They affect to entertain, because they have never questioned, certain theoretical tenets in medical science, but these beliefs do not in any way modify or injure their practice. If we could effectively pass in review the old pathology and the new and estimate their practical results we should, I am convinced be greatly impressed with the need for clinical gynæcology saving itself by its own scientific clinical work, not by faith in any pathological creed

THE OLDER PATHOLOGY

There is such a vast amount of writing on the subject of the etiology and pathology of cancer that in the effort to select typical authorities we are embarrassed, even bewildered. The gynæcologist naturally turns to the authority of the "gynæcology pathologist," whose investigations and speculations are, at least, marked by the conscientious effort to lead up to something with practical and helpful applications towards the solution of problems which meet him constantly in his professional occupations If then, we turn to the publications of the recognised masters who are not only pathologists but have grown old in the constant contribution of the highest practical services to the advancement of obstetrics and gynæcology and whose example has moulded the opinions and practice of their contemporaries and of a younger generation, we may confidently commence with a concise exposition of the opinions of Hegar In his recent works on the "Etiology of Malignant Tumours" he modestly refers to the contributions of W A. Freund and of Czerny as giving him courage to make an attempt at expounding his own views but when we turn to the writings of these authorities and endeavour to form some clear conception of what they intended to contribute to the sum of our knowledge we cannot help feeling that there is some room for a certain sense of disappointment. Hegar thinks we shall not be so very soon in a position to establish the causes which lead to ordinary carcinoma and sarcoma, yet there is no reason to despair "We have made such progress that we may soon be able to formulate our questions," thus clearing the ground for future investigators. In endeavouring to grapple with the subject he calls attention to certain respects in which the theories of Thiersch and

Address in Obstetrics

CARCINOMA IN WOMEN, CHIEFLY IN ITS CLINICAL ASPECTS.

Delivered at the Annual Meeting of the British Medical Association at Manchester July–August, 1902

By WILLIAM JAPP SINCLAIR, M D Aberd,
PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY IN THE OWENS COLLEGE, MANCHESTER.

Eadem orationis virtus atque unguenti nam et male affectos nos juvat, et bene habentes oblectat.—Demophilus.

INTRODUCTORY

Gentlemen —Looking forward to standing in the position occupied once by such men of mark in their generation as Thomas Radford Matthews Duncan, and Robert Barnes I am keenly alive to the fact that I do not owe the position, as they did, to a wide reputation and well earned professional distinction. All the more, perhaps, having resolved to do the best I am capable of in the position, am I deeply grateful to the Council of this Association and to my too indulgent friends and neighbours whom chiefly I have to thank for the great honour conferred upon me.

In ruminating over the limited range of my intimate professional knowledge for a suitable theme for an address I had to keep in mind that the subject must be in the highest degree important in itself in order to be worthy of the occasion it must be of wide interest in order to arrest the attention of those who are engaged in the practice of obstetric medicine in its widest sense and it must, if possible, be not a mere professional essay but have some important object and aim. I felt, also, that it would be an advantage to myself in preparing an address if I could discover a subject which had occupied my own thoughts in a special degree in the course of my practical professional work. With such conditions and many others essential to the most modest fulfilment of my task I felt that my undertaking was extremely formidable, but I knew that I could rely upon your forbearance and upon the intrinsic interest of my subject. I have chosen for the subject of my address Carcinoma in Women, chiefly in its Clinical Aspects that is very largely from the standpoint of the medical practitioner

Apology and justification.—It is generally believed that carcinoma of the sexual organs of women is as cancer occurring in men and to this extent, therefore, the subject is not one of obstetric medicine pure and simple. But malignant disease has a tendency to affect certain organs in women to an extent and with a relative frequency unknown in the other sex, and the clinical facts in the typical cases of cancer of the uterus make up a *tout ensemble* an association of syndromata, a personality of the disease, that distinguish it from the malignant disease of any other organ. Then the frequency of its occurrence, the sex of its victims, and the pitiful character of its course from the social point of view lend it an interest and a pathos almost entirely its own.

If carcinoma of the uterus be the same disease as cancer in general, may not this individuality or personality of the malady make it the key to the situation? The frequency with which the disease occurs in a medical practice, the comparative similarity pervading the cases amidst individual differences, the facility with which operations can be performed and therapeutic agents employed, the possibility of careful clinical investigation and observation of cases in which the disease recurs and of cases immune from recurrence, are all circumstances which attract attention to this special form of malignant disease render it a comparatively easy subject for inductive reasoning and therefore make of it perhaps the most promising field for clinical research.

Contrast between pathologists and clinical workers —We must have observed a tendency to establish a contrast, or at least a certain degree of antithesis, betwixt clinical and scientific work. It was the devotion of the gifts of genius of the highest intellectual endowments, to clinical investigation which lent dignity to the labours of former generations of physicians and surgeons and made their councils fruitful in conferring permanent benefits upon humanity Enlightened and patient industry and success in the observation and treatment of disease were the long and tedious, but the only sure way to professional distinction and honour But now, since the advent of the modern developments of pathology, and especially of bacteriology the unknown or misunderstood is accepted as magnificent by the whole medical profession, and a certain distinction can be achieved without much talent or industry the microtome and the cultivation tube—though work connected with them often resembles a sad mechanic exercise—have provided a royal road for many men into fields of clinical work which they have not known how to cultivate. They have shirked their apprenticeship to clinical medicine yet they claim the consideration and emoluments due to the skilled and experienced journeyman.

But while I put in this word of protest against anything that may appear directly or indirectly to derogate from the dignity and from the appreciation of the usefulness of scientific clinical work I claim to hold in as high esteem and admiration as any man can the magnificent intellectual labours of the pioneers and masters of modern pathology and bacteriology Both clinicians and pathologists require all the mental endowments that Nature confers upon her most favoured in order to investigate the causes of disease and apply the remedies and there is no room for formal or implied depreciation of the work of either Still we may institute comparisons.

Pathology and clinical gynæcology —There is a general and a special aspect of the subject which we may examine in proportions suitable to the occasion (1) the investigation of the etiology and pathology of cancer in general and (2) the consideration of cancer of the uterus in particular The practical gynæcologist may ask, What have investigations and researches into the etiology and pathology of cancer done for clinical gynæcology? The answer must be guarded at this stage at least. A late distinguished gynæcologist once said in his haste that a knowledge of anatomy was positively misleading with regard to the surgery of the pelvis. It can hardly be alleged that pathology has been misleading to the gynæcologist, for he has never trusted to its guidance. Men are wiser than their creeds" they hold pious opinions in religion which fortunately they never put into practice. They affect to entertain, because they have never questioned, certain theoretical tenets in medical science, but these beliefs do not in any way modify or injure their practice. If we could effectively pass in review the old pathology and the new and estimate their practical results we should, I am convinced be greatly impressed with the need for clinical gynæcology saving itself by its own scientific clinical work, not by faith in any pathological creed

THE OLDER PATHOLOGY

There is such a vast amount of writing on the subject of the etiology and pathology of cancer that in the effort to select typical authorities we are embarrassed even bewildered. The gynæcologist naturally turns to the authority of the gynæcology pathologist, whose investigations and speculations are, at least, marked by the conscientious effort to lead up to something with practical and helpful applications towards the solution of problems which meet him constantly in his professional occupations If then, we turn to the publications of the recognised masters who are not only pathologists but have grown old in the constant contribution of the highest practical services to the advancement of obstetrics and gynæcology and whose example has moulded the opinions and practice of their contemporaries and of a younger generation, we may confidently commence with a concise exposition of the opinions of Hegar In his recent works on the Etiology of Malignant Tumours" he modestly refers to the contributions of W A. Freund and of Czerny as giving him courage to make an attempt at expounding his own views but when we turn to the writings of these authorities and endeavour to form some clear conception of what they intended to contribute to the sum of our knowledge we cannot help feeling that there is some room for a certain sense of disappointment. Hegar thinks we shall not be so very soon in a position to establish the causes which lead to ordinary carcinoma and sarcoma, yet there is no reason to despair We have made such progress that we may soon be able to formulate our questions," thus clearing the ground for future investigators. In endeavouring to grapple with the subject he calls attention to certain respects in which the theories of Thiersch and

Cohnheim, the two most frequently accepted explanations of the genesis of carcinoma, stand in direct opposition to one another.

Thiersch lays chief stress upon the failure of that resistance to the increase of cells which is normally brought to bear by the tissues. He must therefore assume that the ordinary epithelial cells possess a great energy towards proliferation and that this energy is brought into play by a depression of the power of resistance of the tissues. According to Cohnheim such a strong proliferation as is necessary to the formation of the tumour cannot be effected by the cells of the tissues post partum. Only embryonic cells are capable of performing such a task, and it is these which form the basis of malignant tumours when they still remain behind in the body with their energy retained in full. Both authorities leave out of consideration the fact that the cells of a malignant growth increase rapidly but are never completely developed, and the capacity for differentiation on the part of embryonic cells is their most remarkable characteristic.

Keeping this fact in mind some more recent writers on the subject try to reconcile or to evade the differences and difficulties by supplementary theories stated in the language of poetry. Hansemann speaks of an "anaplasia of the cells" by which their energy towards differentiation suffers an injury but their capacity for maintaining a separate existence is increased. Hauser speaks of a "parasitic character," not in the most recently accepted sense. Here the old doctrine comes again into view according to which cancer presents a sort of parasitic growth—*ein Schmarotzer gewachs*—which gradually devours the host which entertained it. It is "an emancipation of the cells from the laws of physiological life," according to one pathologist, "a sort of anarchy," according to another, or "a riotous proliferation", and, in the opinion of still another, it is an "unconscious memory of cells and tissues and an attempt to recover their lost independence of action." Whatever felicity of literary expression may be attained in the exposition of these opinions the most of the theories amount to this, that the cell acquires a peculiar energy which it had not before possessed, all of which brings us back to the rapid proliferation, the depression of the powers of resistance, and the decrease in the faculty of differentiation.

We have, then, to establish how these peculiarities come into existence. Hegar has no difficulty in finding some causes which rob the cells of their capacity for arriving at complete development. He discusses many of them—advanced age, purely mechanical influences interference with general nutrition, the ravages of contagious disease. He touches incidentally upon some of the puerile attempts to generalise from a too limited number and variety of facts, and from the misinterpretation of even these, explanations of the causes of things, such as we generally consider the products of the Age of Faith rather than of the scientific intellect of the nineteenth century.

Hegar's special contribution here is an examination of examples of the growth of epithelium, such as in abnormal growth of hair, even when wasting of the body generally is going on. That there is some sort of relationship between the anomalies of growth and development and the occurrence of tumours, often observed in the same individual, there is no room for doubt. 'Energetic proliferation may be associated with depressed differentiation and *vice versâ*." But Hegar does not possess the type of intellect that can harbour illusions with regard to facts, and he admits that of casual relationship between these phenomena and the growth of malignant tumours there is no proof whatever ("*Allein für einen Kausalnexus fehlen alle Beweise*"). The same judgment is brought to bear upon Birch-Hirschfeld's theory of a symbiosis, perhaps the most transcendentally remote from the clinical standpoint and yet probably the progenitor of our newest theories and researches. Symbiosis, to which he refers the origin of cancer, is a sort of fecundation whereby the tissue cell acquires a greater independence and becomes a sort of parasite. The theory assumes the presence of a micro-organism. If this were demonstrated to be present the problem would be solved in the form of a parasitic theory of the purest kind. But all attempts to demonstrate the presence of such an organism have been in vain. We must therefore content ourselves with the alternative theory whereby the tissue cell possesses *a priori* the capacity of increase necessary to the production of malignant tumours. This theory can be supported by many striking facts, such as the wear and tear of epidermis and the restoration of the epithelium of mucous membranes. But, again, all causal-nexus fails, increase of cell growths leads to the formation of hypertrophies and benign tumours, not to carcinoma and sarcoma.

Hegar attempts to bring the theoretical and practical together. As to treatment he concludes that he must confine himself to a few points which arise out of what he has endeavoured to establish concerning causation. Prevent irritation, give special attention to nutrition, keeping in mind individual characteristics, occupation, time of life, prevent infection as far as possible from such diseases as lues and gonorrhœa. But our knowledge of the influence of micro-organisms, and especially of the products of their metabolism, is as yet too defective to enable us to be more precise on the subject of prophylaxis. Finally, he agrees with Czerny and W. A. Freund in their comparative optimism, as also in their warning with regard to surgical treatment, not to be discouraged or to "throw up the sponge" prematurely. His colloquial figure of speech "*Die Flinte nicht zu früh ins Korn zu werfen*" amounts to much the same thing. When we think of the surgical measures in vogue among the younger men in Germany at the present day we can only reflect that there was surely in the history of surgery never a more superfluous exhortation.

To the recent utterance of W. A. Freund, formerly of Strassburg, we turn with a lively expectation of a clear statement of our present position with regard to pathology and for such practical guidance for the future as the long and honourable career filled with the thought and action of an eminently practical man can afford us. Freund also begins with the encouraging description of cases of permanent cure of cancer of the uterus. Still, the remote results of such operations remain unsatisfactory even though we can perform the most radical of operations by clearing out all the female sexual organs from the pelvis without fatal consequence. Wherein lies the cause of failure? Is it in the nature of the disease or in the method of operating? Does the cancer pathology of the present day afford us any sure indication for a rational and prophylactic treatment? Freund proceeds to pass in review the various theories, past and present, which have been formulated regarding the histogenesis, etiology, and clinical features of cancer. He proves that he himself has preserved to a remarkable degree the capacity for criticism as well as for the generous appreciation of the work of younger men. He even quotes Marchand's dictum that the meaningless collective term "carcinoma" is an inherited burden which we still drag along with us. The most recent investigations have shaken, he might have said shattered, the whole blastodermic theory. The general effect of the review is to give the impression that modern German research and experiment have produced a process of iconoclasm. It has pulled down the old and mighty authorities from their seats, and has set no meek ones in their place. The whole situation is summed up somewhat cynically, but unfortunately too truthfully, by one of the disputants. He says "For us the catchwords 'development from the connective tissue, development from the epithelium,' with which the controversy has been conducted, are devoid of any real meaning", and he describes himself as the idle spectator at a game of bluff which is conducted on both sides with great zeal for science, but in which only false coin is given and taken by both sides with solemn equanimity. So now the old etiology and pathology of cancer pass away into the limbo of human futilities, holding in their clutch no inconsiderable portion of the new speculations and researches. The late Professor Huxley, in arguing against the continuance in our schools and universities of the old classical education, once said that he could construct a grammar of palæontology which would be more useful than the Greek grammar and fully as efficient for the training of the mental faculties of the young. When we think of the sufferings of successive generations of students of medicine in trying to master the blastodermic theory of malignant neoplasms let us seek comfort in the reflection that at least it has had some of the educative influence of Huxley's Grammar of Palæontology. In an eloquent passage at the close of an admirable address Freund said "I myself can no longer share in this serious and difficult work. To perform it becomes the task of a younger generation, for whom I wish from my heart success in the conquest of this promised land—the cure of cancer of the uterus. I would be happy if, like Moses, I were permitted to gaze upon it from afar." We can only sadly reflect that we also might be encouraged and comparatively happy if we could only claim with conviction the right to call it the Promised Land and believe that it will ever be occupied.

THE NEW PATHOLOGY

It would take us too far away and for too long a time from the clinical consideration of the subject to go into detail on the newer etiology and pathology of cancer in general and the disease as it affects the female sexual organs in particular But it may be as well for the sake of completeness, and on account of its alleged bearings on the practice of to-day to glance at the chief features of the more recent research and controversy Is the cause of malignant disease a vegetable parasite or blastomycete as suggested by Russell 10 or 12 years ago and worked out by San Felice and many others? Are the cancer bodies" animal parasites?—a theory maintained by Gaylord and supported by much persevering and ingenious observation and experiment. Is it an infectious disease most nearly resembling tubercle and syphilis? or is the cause still entirely unknown or merely guessed at as possibly the result of local or general changes in the nervous system governing the growth, the nutrition and involution of organs and tissues? It would be impossible within my limits and with the objects in view to discuss all this in detail but we may glance at the work of one or two individuals and inquire in what relation their results stand to the clinical observation and the treatment of disease.

Leopold of Dresden, after several years of observation and experiment, placed the results of his labours before the profession at the International Congress held at Paris in 1900, and he returned again to the subject at the Congress of German Gynæcologists held at Giessen last year His conclusions amount to this that blastomycetes may be the cause of malignant new growths in man that they may convey the disease by inoculation from man to animals producing exactly similar new growths which are fatal to the animals affected. Among his experiments Leopold mentions the implantation into a rat of tissue from carcinoma of the ovary The animal died in 61 days from a tumour of the size of a walnut which was found to be an adeno-sarcoma. It will thus be seen that Leopold like some other experimenters in order to support his conclusions, must give up the distinction between carcinoma and sarcoma. This may be right and a step towards truth and simplicity or it may have been accepted by the author under stress of circumstances like the poet succumbing to the inexorable demands of rhyme at the expense of the sense or it may only imply which is most probable of all and certainly true that it is not always possible to distinguish between carcinoma and sarcoma by the aid of the microscope alone

In referring to this subject in a recent discussion Menge expressed the opinion that such experiments produce merely granulation tissue with giant cells and he further says

If Leopold holds to his belief in the specific nature of his cancer producers he must admit the identity of carcinoma and sarcoma." W A. Freund's opinion of such experiments may be inferred from his oracular advice, when concluding his appreciation of Leopold's work Wait and see' (*Abwarten!*)

With regard to the parasitic theory of cancer some very confident statements as to progress in discovering the causation come to us from America. At the last meeting of the American Gynecological Society one of the speakers gave typical expression to our vague hopes and aspirations In the course of a paper on Hysterectomy for Uterine Cancer he said 'Are we not justified in the hope that the so-called parasitic theory of the origin of cancer may evolve something? The solution of the question depends upon the bacteriologist and pathologist. We can but look upon the subject with some seriousness when the great State of New York has considered it of sufficient importance to establish a pathological laboratory for the study of the etiology of cancer Dr Gaylord of that institution has reported that he has found the protozoon." During the discussion which followed Dr Matthew D Mann Professor of Gynæcology in the University of Buffalo said I know the profession is not ready yet to accept the evidence of what has been done in Buffalo but personally I feel quite convinced that in the State Laboratory the cause of cancer has been discovered." Of certain work in support of the yeast theory of the etiology of cancer it has recently been said Roncali apparently thinks the *ipse dixit* of enthusiasm is an adequate substitute for the details of a scientific proof." But here is apparently independent evidence from a witness of repute which is bound to arrest attention. Nevertheless, a witness who knows the facts and whose evidence must weigh fully more with us than even the one just quoted—I allude to Senn of Chicago—said even more recently that intra-parenchymatous injections of animals were of no use as a proof of anything and that the parasitic origin of carcinoma has not been established by experimental research bacteriological or histological, or by implantations or inoculation experiments This year we have the report of the Cancer Commission of the Harvard Medical School. It informs us that the work done during the past two years in the study of the etiology of cancer has been wholly negative in its results in the sense that an increasing doubt has been thrown upon the parasitic origin of the disease and upon the pathological significance of so-called cell inclusions. An opinion is given that the long series of admirably conducted experiments went to show that the search for a cause of cancer has not been furthered and is not likely to be, by a continued prosecution of research on the lines just mentioned. The Director of the State Laboratory at Buffalo says on the other hand, that the results of the past year's work have been to strengthen the conviction that cancer is an infectious disease.

A witty Frenchman once said of French politics "*Plus ça change plus c'est la même chose*' and the sentiment might not inappropriately be applied to the researches into the etiology and pathology of cancer of the uterus. At the foundation of every hypothesis there is the hope that if only a cause could be discovered a remedy might be found in the working out of every theory there is a certain amount of observation and research vitiated by some preconception, then a war of opinion more or less in the nature of an acrimonious logomachy between rival schools But it is the same thing Even if it were possible to reconcile some contradictions we are not in sight of any causal nexus between the clinical phenomena of the disease and the alleged factors in its production and still further away from any hint of the bearing on the pathology at present in vogue upon any definite therapeutic measures No reasonable man will condemn the new pathology it is a grand monument of the patient and industrious application of the highest scientific imagination and the capacity for research to the solution of a problem But it has been hitherto as futile as the old. From a thirty years war of opinion as to the interpretation of phenomena no great pathologist brings home *spolia opima*, we can hardly reckon among our actual acquisitions mere flotsam and jetsam from the troubled sea of controversy One recent writer says that probably we have reached finality as regards the mere examination and classification of cancerous growths as far as the microtome and microscope are concerned and further knowledge must be sought for by way of experimental investigations. But on what principles are we to go beyond the experiments already made? We are probably in the position of the German peasant who on seeing a railway train for the first time exclaimed in amazement

Es müssen doch Pferde darin sein (But after all there must be horses in it) Let us hope we have also in store for us the surprise of seeing the application of some genuinely novel principles and methods to the elucidation of this dark problem.

MISCELLANEOUS THEORIES

But the more sanguine may think it worth while to inquire if there is not some room for hope in the further development of theories concerning individual causes. If you can find an individual cause or group of causes then the solution is simple—remove the cause. If the cancer is produced by eating too much animal food abstain and you are safe If the cause of the malignant tumour be the included epiblast or a group of mysterious parasites which you entertain involuntarily like keeping an inaccessible case of dynamite in your cellar ignorance would be bliss but if it is caused by the prodigal consumption of chloride of sodium the sooner you know and give effect to your knowledge the better After the admirably reasoned argument of Dr J F Payne in a recent discussion on carcinoma we shall probably hear comparatively little in the future, at least in this country of the vague statements on the influence of woods and river courses in producing cancer This much may be said, while admitting that there is room for a rational attempt to get at the real import of cancer localities."

The recent suggestion that the arsenic which we all take into our systems, voluntarily or otherwise may be a contributory cause to the increase of cancer is at least startling

It used to be considered the one drug that had some specific effect as a cure and it was the sheet anchor of the cancer quacks But strange vicissitudes occur in the history of unfounded hypotheses A century ago osteomalacia was believed to be the cause of certain death after Cæsarean section, nowadays the operation, as modified by Porro, is the certain cure for osteomalacia. But it is useless to pursue this line of argument, I believe we are right in assuming that there is no hope for the solution of the cancer problem in any of the theories of individual causes hitherto advanced. There is a parity of reasoning in the support of many of them with Burns's explanation of the causation of certain great qualities in Scotsmen "Tell me whisky's name in Greek, I'll tell the reason"

CANCER OF THE UTERUS NOT AS A GROWTH BUT AS A DISEASE

We search, then, in vain through the recent manuals of gynæcology, and even of pathology and the records of pathological investigation for any hint of progress in the evolution of an etiology of malignant disease of the internal sexual organs of women. Of histology there is enough and to spare, but of pathology in the narrower sense there is little to arrest attention, much less to satisfy, and there is absolutely nothing to indicate an advance from the position of a former generation of pathologists The nomenclature is new, the thoughts and principles are old There would, in fact, be a certain amount of truth in the allegation that the diligent pursuit of the histology of malignant growths and other tumours has distracted the attention, the activities, and the energy, to say nothing of the intellectual force, which might have led to a true pathology of cancer of the uterus by fixing the attention upon structure, growth, and extension in relation to clinical phenomena. We have heard too much of cancer as neoplasm, too little of it as a disease If, now, we set aside all considerations of the etiology and pathology of cancer of the uterus and keep in mind only the clinical aspects of the disease, we see much ground for congratulation on the achievements of the last quarter of a century The clinical work has been wholly surgical. What is not surgical is futile—it is hardly knowledge.

What has been accomplished?—It is nearly 30 years since, as house surgeon to a gynæcologist of great local repute, I had every opportunity of observing the treatment of cancer of the uterus, a disease which when a student I had never once seen diagnosed by a clinical teacher The routine method was to clear away some of the débris of tissue from the invaded portion of the cervix and apply a liquid which had at the time a more general application in the treatment of certain diseases of the skin The treatment was painful, and that was all No patient was kept in the hospital to die, and I need hardly say that no one received appreciable benefit. Next came the period of bromum and other specifics equally futile.

A few years later I had the opportunity of witnessing the operations by the galvanic écraseur of the late Professor Carl Braun von Fernwald in the Vienna General Hospital He obtained a wonderful degree of success in arresting for years, and sometimes permanently, the progress of the disease by removing the vaginal portion of the uterus when that was the only part involved. Next Schroeder of Berlin practised and advocated the supra vaginal amputation of the cervix. The practice has been continued to the present time by some of Schroeder's pupils, notably by Hofmeier and Winter

Next came the period of progress with the operation of total extirpation Many hesitated to attempt it owing to the immediate danger But the technique rapidly improved and it soon became the generally accepted operation, because it afforded the best grounds for hope of conferring prolonged benefit or of definitely curing the patient. Whatever we may think of the remote results of our surgical work no one who knows the history can deny that the reduction in the immediate mortality from this operation marks one of the greatest triumphs of modern surgery

Vaginal hysterectomy, when the disease is confined to the uterus, is not now more dangerous than is an ordinary ovariotomy The mortality, which at one time was over 30 per cent., has now sunk to 3 or 5 or 7 per cent., according to the extent of the disease and the concomitant complications or derangements of health In recent years there has been a wave of mental depression passing over the gynæcological world on account of the unfavourable remote results of vaginal hysterectomy for cancer, and the most optimistic will admit that there has not been much ground for exultation. At a recent congress of American gynæcologists one of the eminent members said "There are some men who claim for total extirpation of the uterus the happiest results Other men have looked upon the matter with utter hopelessness I am sorry to say that I have brought myself among the latter class from bitter experience." Hofmeier at the last Congress of German Gynæcologists declared that the present professional opinion and practice amounted to a declaration of "bankruptcy" of the radical vaginal operation as practised for the last 15 years Of this statement Fritsch remarked "It has been said that we have gone bankrupt with our vaginal total extirpation, and that its place must be entirely occupied by the abdominal method, and this has been said about an operation from which better results have been obtained than from any other cancer operation whatever" But so far from the pessimistic view being the true one the results obtained by many of the best-known operators continue to improve and to give the greatest encouragement to continued efforts in the future They are obtaining better immediate results and the number of "cures" increases—that is, the percentage of immunity for at least five years after operation becomes greater The percentage of cases operable when first seen also increases because the patients come earlier for treatment and improvements in technique have extended the indications The proof of all this lies in the statistics of carefully reported work done under circumstances in which the sources of error are reduced to the minimum. We may select examples from every country in Christendom, which now includes America, and the lessons taught by all are the same

Von Ott of St. Petersburg gave the figures for Russia in the Section of Gynæcology at Paris two years ago He mentioned 1000 cases of the radical vaginal operation, with a mortality of 10 per cent. for the work of many operators Von Ott himself had performed 189 operations with a mortality of 1 6 per cent. For his own statistics he had experience of six years of freedom from recurrence, equal to 29 per cent. of cures, according to the conventional method of reckoning He had known cases of permanent immunity from recurrence which appeared to be hopeless before operation. Olshausen of Berlin operates now in 50 per cent. of all cases, instead of in 31 per cent. as formerly Recurrence is not uncommon between three and seven years after operation, but very rare afterwards. In 671 cases operated upon in the course of nine years the mortality was 6 per cent. In the last six years, between 3 and 4 per cent. In the last three years there were 291 cases with a mortality of 5 per cent. As to recurrence, over 36 per cent. of the cases were free after five years, after two years free from recurrence, 74 per cent., after three years, 62 6 per cent., after five years, 38 8 per cent. Zweifel of Leipsic now operates on 50 per cent. of all cases presenting themselves for treatment. Formerly he could operate on only 27 per cent. He considers the 27 per cent. of Leipsic a low figure compared with Berlin. Zweifel in the course of four years performed 219 vaginal operations with a mortality of 5 48 per cent. Chrobak, in Vienna, operated in 213 cases with a mortality of 5 6 per cent. The proportion of operable cases increased from 15 to 29 per cent The percentage free from recurrence after five years was 34 6 In Schauta's clinic in Vienna 273 operations were performed The mortality for the vaginal operation was 10 per cent., for the abdominal operation 60 per cent. The mortality in uncomplicated cases operated on by the vaginal method was 4 6 per cent. Of these patients 36 per cent were permanently cured When the cancer extended beyond the uterus the primary mortality was 23 per cent. and the permanent cures were 7 per cent Reipen gives the figures for Halle The operators were Kaltenbach and Fehling There were 303 cases and the operation mortality was 6 6 per cent. There was no recurrence within five years in 25 per cent of the cases In carcinoma of the body of the uterus alone there was no recurrence in 75 per cent. Cullen in America had no recurrence in 66 per cent. of cases of cancer of the body In 73 cases of cancer of the cervix he had 20 per cent. of non recurrence. Kelly of Baltimore had had 63 per cent. of freedom from recurrence after six years in cancer of the body, in his cases of carcinoma of the cervix there was immunity from recurrence for from three to six years in 28 per cent. Kelly offers his testimony as to freedom of the pelvic glands from infection when the disease is confined to the uterus and therefore operable in the first degree. Hense gives remarkable evidence as to the influence of the climacteric in preserving from recurrence In 73 cases of post-climacteric operation there was permanent freedom from recurrence in 50 per cent. Winter reports from Berlin 308 operations with a mortality of 50 per cent. Recurrence took place in nearly 70 within five years, and there were nearly 30 per cent. of permanent cures. Of the cases in which the operation could be effected in sound tissue the proportion of cures was 33 per cent. Winter remarks on the frequency of recurrence in the cicatrix. As representatives of Italy we may quote Spinelli and Mangiagalli The former reports 41 operations with a primary mortality of 2 4 per cent. but the cures were only 8·9 per cent. Mangiagalli had 127 cases with a mortality of 8 6. Only 17 patients were free from recurrence after three years. In his cases recurrence was *always* in the cicatrix. In this country Lewers traced the history of 40 cases operated on radically per vaginam with a primary mortality of 7 per cent. There was freedom from recurrence in 27 5 per cent. from two to seven years. In 11 cases of cancer of the body five of the patients were well from four to seven years after operation.

These illustrations of work done might be multiplied to an indefinite extent, but enough has been set down to support the statement that there is ground for encouragement, not for depression much less for despair in the recent history of vaginal hysterectomy for cancer Each story from which the bare figures have been culled contains its own lessons and its message of hope, encouraging us to persevere in the course on which we have entered. At the first glance there may appear to be but cold comfort in the figures, but we should remember that every woman cured" in even the conventional sense has been saved from a lingering and painful death To our resources that will enhance the value of surgical interference in the future there has been in recent years no more valuable contribution than the improvement in technique introduced by the late Professor Schuchardt of Stettin. The most remarkable figures of all are those given by Schuchardt as the results of the paravaginal operation. The best results before were those of Leopold in Dresden, who with an operability of 20 4 per cent had 50 per cent. of conventional cures." Schuchardt raised the operability to 61 per cent. and had conventional cures to the extent of 40 per cent. In easy cases he had the astonishing result of 60 per cent. of cures.

Reaction.—One of the results of the depression arising from the recognition of the unfavourable remote results of vaginal hysterectomy has been a rush especially in Germany to the extreme verge of the practical in dissecting out not only the internal sexual organs but the whole of the lymphatics and cellular tissue of the pelvis. This has been declared to be justified by the belief that better remote results would be obtained than by vaginal hysterectomy

From a careful and laborious attempt to keep up with the record of proceedings I have no hesitation in saying that a large portion of the extended radical abdominal hysterectomies for cancer are homicidal vivisections which nothing hitherto advanced in their support appears to palliate, much less to justify Most of the cases recorded have been too far advanced for any operation however radical. 'The radical nature of these operations," says one German critic, is expressed only in the sad immediate and remote results a high primary mortality and injuries to the ureters and bladder in those who survive for a time. The operators profess to dissect out the pelvic lymphatic glands, iliac, hypogastric, sacral, inguinal, lumbar, and they resect the ureters and reimplant them in the bladder when they interfere with the scope of their proceedings. The immediate mortality is terrific but then, as Jacobs said at Amsterdam the operation mortality is no longer an argument capable of arresting our efforts, and so far as experience of the remoter results has ripened for guiding inference all admit that the patients who escape with their lives from the operations, occasionally reckoning only the possession of a permanent urinary fistula or the loss of a kidney among the consequences, are no better off in relation to recurrence than are those who have undergone the comparatively safe operation of radical vaginal extirpation.

There appears at the present time to be no visible limit to operations for cancer in the judgment of some of our contemporaries. The title of one very recent contribution to a gynæcological journal must suffice for calling attention to *Fortschritt* in the direction of vivisection Simultaneous occurrence of cancer of the uterus and of the stomach—abdominal total extirpation of the uterus, gastrectomy with gastro-jejunostomy " This operative work all at one sitting.

THE FUTURE OF TREATMENT AND THE AIMS OF CLINICAL RESEARCH.

From all that has been said it must be obvious to those who care to listen to opinions of mine that I firmly believe the presently existing pessimism is not justified by the facts, that there is much reason for encouragement to greater efforts in the future, and that our hopes must rest on early vaginal operation, not on the so-called extended radical abdominal sections. We may look forward to the future with a certain degree of confidence that considerable achievements are still before us, even though the pathologists do not succeed in working out a theory of the causation with practical applications to therapeutics. In saying so I do not profess to assume the functions of the prophet. We can all enlighten the present on subjects which are the chief interest of our lives, and any real insight into the present is bound to shed some light on the immediate future by the ordinary process of cautious inference. Among the preliminary considerations which call for attention comes the question Is cancer of the uterus on the increase? My own firm conviction for a long time has been that it is not, in spite of all allegations to the contrary

The late Sir Spencer Wells in the Morton Lectures of 1888 gave rather an alarmist account of our prospects but we must all welcome with a sense of relief the recent statement of Dr Tatham at the Chelsea Clinical Society According to Dr Tatham cancer in women is not increasing at the same rate as is cancer in men. The increase in men and women respectively was in 1891–1900 as 147 to 74 There is not time to argue the matter out, but it seems reasonable to attribute the disparity of increase to a considerable diminution in the extent of cancer of the uterus and mamma. All this is especially reassuring when we remember that the disease is now almost always diagnosed, at least in its later stages whereas in former times it was in many cases overlooked even when it was about to produce, or had produced a fatal result. For example, if we keep in mind the cases in which there was little ulceration and much infiltration producing occlusions of the ureters and fatal uræmic convulsions, cases of early peritonitis and other complications, we must believe that the more general capacity for correct diagnosis has added considerably to the apparent increase of malignant disease in women.

If as I firmly believe, cancer of the cervix is a different disease from cancer of the body and is a *morbus miseriæ* like osteomalacia, leprosy and pellagra, it is bound to decrease as the social condition, the physical well being, the freedom from worries and the consequent comparative happiness of the people improve and become more general, if not universal.

Cancer of the cervix uteri occurs almost exclusively among the poor the chronically overworked and underfed—among poor prolific women harassed, worried drained by lactation, and reposeless. That fissures of the cervix, neglected lacerations, tissue changes in the cervix from flexions, irritations from venereal diseases remnants of puerperal sepsis affect the cervix I have myself no doubt whatever There is no time to argue the question, but each expression here used embodies an opinion and has the foundations of a thesis which I am prepared to maintain and defend. But we cannot afford to remain supine and inactive while the process of evolution is going on. We have seen disease eradicated in this country by social legislation—for example, mollities ossium, but no legislation that we can foresee will relieve our fellow-countrywomen from the physical effects and the cares of large families or save them from the consequences of their own negligence and from marital cruelty and selfish indulgences.

Our hopes of immediate amelioration rest therefore on surgery.—We must rely not on the extension of operative procedures into the brilliance of vivisections, but on the united efforts of all concerned to bring the cases under surgical treatment at the earliest possible stage. We labour at present under considerable disabilities.

1. The patients are not so well trained and disciplined as German and other women in continental Europe. They naturally hesitate when they think of going to a medical man to tell of their symptoms and they neglect the most ominous symptoms with a light heart because they suffer no pain. The consequence is that as a rule our cancer patients consult the medical practitioner when it is clearly too late to do any operation justifying the hope of cure or even

It used to be considered the one drug that had some specific effect as a cure and it was the sheet anchor of the cancer quacks But strange vicissitudes occur in the history of unfounded hypotheses A century ago osteomalacia was believed to be the cause of certain death after Cæsarean section, nowadays the operation, as modified by Porro, is the certain cure for osteomalacia. But it is useless to pursue this line of argument, I believe we are right in assuming that there is no hope for the solution of the cancer problem in any of the theories of individual causes hitherto advanced. There is a parity of reasoning in the support of many of them with Burns's explanation of the causation of certain great qualities in Scotsmen "Tell me whisky's name in Greek, I'll tell the reason"

CANCER OF THE UTERUS NOT AS A GROWTH BUT AS A DISEASE

We search, then, in vain through the recent manuals of gynæcology, and even of pathology and the records of pathological investigation, for any hint of progress in the evolution of an etiology of malignant disease of the internal sexual organs of women. Of histology there is enough and to spare, but of pathology in the narrower sense there is little to arrest attention, much less to satisfy, and there is absolutely nothing to indicate an advance from the position of a former generation of pathologists The nomenclature is new, the thoughts and principles are old There would, in fact, be a certain amount of truth in the allegation that the diligent pursuit of the histology of malignant growths and other tumours has distracted the attention, the activities, and the energy, to say nothing of the intellectual force, which might have led to a true pathology of cancer of the uterus by fixing the attention upon structure, growth, and extension in relation to clinical phenomena. We have heard too much of cancer as neoplasm, too little of it as a disease If, now, we set aside all considerations of the etiology and pathology of cancer of the uterus and keep in mind only the clinical aspects of the disease, we see much ground for congratulation on the achievements of the last quarter of a century The clinical work has been wholly surgical. What is not surgical is futile—it is hardly knowledge.

What has been accomplished?—It is nearly 30 years since, as house surgeon to a gynæcologist of great local repute, I had every opportunity of observing the treatment of cancer of the uterus, a disease which when a student I had never once seen diagnosed by a clinical teacher The routine method was to clear away some of the débris of tissue from the invaded portion of the cervix and apply a liquid which had at the time a more general application in the treatment of certain diseases of the skin. The treatment was painful, and that was all. No patient was kept in the hospital to die, and I need hardly say that no one received appreciable benefit. Next came the period of bromum and other specifics equally futile

There was freedom from recurrence in 27 5 per cent from two to seven years. In 11 cases of cancer of the body five of the patients were well from four to seven years after operation.

These illustrations of work done might be multiplied to an indefinite extent, but enough has been set down to support the statement that there is ground for encouragement, not for depression much less for despair in the recent history of vaginal hysterectomy for cancer Each story from which the bare figures have been culled contains its own lessons and its message of hope, encouraging us to persevere in the course on which we have entered. At the first glance there may appear to be but cold comfort in the figures, but we should remember that every woman cured" in even the conventional sense has been saved from a lingering and painful death To our resources that will enhance the value of surgical interference in the future there has been in recent years no more valuable contribution than the improvement in technique introduced by the late Professor Schuchardt of Stettin. The most remarkable figures of all are those given by Schuchardt as the results of the paravaginal operation. The best results before were those of Leopold in Dresden, who with an operability of 20 4 per cent had 50 per cent. of conventional cures. Schuchardt raised the operability to 61 per cent. and had conventional cures to the extent of 40 per cent. In easy cases he had the astonishing result of 80 per cent. of cures.

Reaction.—One of the results of the depression arising from the recognition of the unfavourable remote results of vaginal hysterectomy has been a rush, especially in Germany to the extreme verge of the practical in dissecting out not only the internal sexual organs but the whole of the lymphatics and cellular tissue of the pelvis. This has been declared to be justified by the belief that better remote results would be obtained than by vaginal hysterectomy

From a careful and laborious attempt to keep up with the record of proceedings I have no hesitation in saying that a large portion of the extended radical abdominal hysterectomies for cancer are homicidal vivisections which nothing hitherto advanced in their support appears to palliate, much *less to justify* Most of the cases recorded have been too far advanced for any operation however radical. "The radical nature of these operations, says one German critic, is expressed only in the sad immediate and remote results, a high primary mortality and injuries to the ureters and bladder in those who survive for a time. The operators profess to dissect out the pelvic lymphatic glands iliac, hypogastric, sacral, inguinal, lumbar and they resect the ureters and reimplant them in the bladder when they interfere with the scope of their proceedings. The immediate mortality is terrific, but then, as Jacobs said at Amsterdam the operation mortality is no longer an argument capable of *arresting our efforts* and so far as experience of the remoter results has ripened for guiding inference all admit that the patients who escape with their lives from the operations, occasionally reckoning only the possession of a permanent urinary fistula or the loss of a kidney among the consequences, are no better off in relation to recurrence than are those who have undergone the comparatively safe operation of radical vaginal extirpation.

There appears at the present time to be no visible limit to operations for cancer in the judgment of some of our contemporaries. The title of one very recent contribution to a gynæcological journal must suffice for calling attention to *Fortschritt*" in the direction of vivisection Simultaneous occurrence of cancer of the uterus and of the stomach—abdominal total extirpation of the uterus, gastrectomy with gastro-jejunostomy" This operative work all at one sitting

THE FUTURE OF TREATMENT AND THE AIMS OF CLINICAL RESEARCH.

From all that has been said it must be obvious to those who care to listen to opinions of mine that I firmly believe the presently existing pessimism is not justified by the facts, that there is much reason for encouragement to greater efforts in the future, and that our hopes must rest on early vaginal operation, not on the so-called extended radical abdominal sections. We may look forward to the future with a certain degree of confidence that considerable achievements are still before us, even though the pathologists do not succeed in working out a theory of the causation with practical applications to therapeutics. In saying so I do not profess to assume the functions of the prophet. We can all enlighten the present on subjects which are the chief interest of our lives, and any real insight into the present is bound to shed some light on the immediate future by the ordinary process of cautious inference. Among the preliminary considerations which call for attention comes the question Is cancer of the uterus on the increase? My own firm conviction for a long time has been that it is not, in spite of all allegations to the contrary

The late Sir Spencer Wells in the Morton Lectures of 1888 gave rather an alarmist account of our prospects, but we must all welcome with a sense of relief the recent statement of Dr Tatham at the Chelsea Clinical Society According to Dr Tatham cancer in women is not increasing at the same rate as is cancer in men. The increase in men and women respectively was in 1891-1900 as 147 to 74. There is not time to argue the matter out, but it seems reasonable to attribute the disparity of increase to a considerable diminution in the extent of cancer of the uterus and mamma All this is especially reassuring when we remember that the disease is now almost always diagnosed at least in its later stages whereas in former times it was in many cases overlooked even when it was about to produce, or had produced a fatal result. For example, if we keep in mind the cases in which there was little ulceration and much infiltration producing occlusions of the ureters and fatal uræmic convulsions, cases of early peritonitis and other complications we must believe that the more general capacity for correct diagnosis has added considerably to the apparent increase of malignant disease in women.

If as I firmly believe cancer of the cervix is a different disease from cancer of the body and is a *morbus miseriæ* like osteomalacia, leprosy and pellagra, it is bound to decrease as the social condition, the physical well being the freedom from worries and the consequent comparative happiness of the people improve and become more general, if not universal.

Cancer of the cervix uteri occurs almost exclusively among the poor the chronically overworked and underfed—among poor prolific women, harassed, worried, drained by lactation, and reposeless. That fissures of the cervix, neglected lacerations tissue changes in the cervix from flexions, irritations from venereal diseases remnants of puerperal sepsis affect the cervix, I have myself no doubt whatever There is no time to argue the question, but each expression here used embodies an opinion and has the foundations of a thesis which I am prepared to maintain and defend. But we cannot afford to remain supine and inactive while the process of evolution is going on. We have seen disease eradicated in this country by social legislation—for example, mollities ossium but no legislation that we can foresee will relieve our fellow-countrywomen from the physical effects and the cares of large families, or save them from the consequences of their own negligence and from marital cruelty and selfish indulgences.

Our hopes of immediate amelioration rest therefore on surgery.—We must rely not on the extension of operative procedures into the brilliance of vivisections but on the united efforts of all concerned to bring the cases under surgical treatment at the earliest possible stage. We labour at present under considerable disabilities.

1. The patients are not so well trained and disciplined as German and other women in continental Europe. They naturally hesitate when they think of going to a medical man to tell of their symptoms and they neglect the most ominous symptoms with a light heart because they suffer no pain. The consequence is that as a rule our cancer patients consult the medical practitioner when it is clearly too late to do any operation justifying the hope of cure or even

It used to be considered the one drug that had some specific effect as a cure and it was the sheet anchor of the cancer quacks But strange vicissitudes occur in the history of unfounded hypotheses A century ago osteomalacia was believed to be the cause of certain death after Cæsarean section, nowadays the operation, as modified by Porro, is the certain cure for osteomalacia. But it is useless to pursue this line of argument, I believe we are right in assuming that there is no hope for the solution of the cancer problem in any of the theories of individual causes hitherto advanced. There is a parity of reasoning in the support of many of them with Burns's explanation of the causation of certain great qualities in Scotsmen "Tell me whisky's name in Greek, I'll tell the reason"

Cancer of the Uterus not as a Growth but as a Disease.

We search, then, in vain through the recent manuals of gynæcology, and even of pathology and the records of pathological investigation for any hint of progress in the evolution of an etiology of malignant disease of the internal sexual organs of women. Of histology there is enough and to spare, but of pathology in the narrower sense there is little to arrest attention, much less to satisfy, and there is absolutely nothing to indicate an advance from the position of a former generation of pathologists The nomenclature is new, the thoughts and principles are old. There would, in fact, be a certain amount of truth in the allegation that the diligent pursuit of the histology of malignant growths and other tumours has distracted the attention, the activities, and the energy, to say nothing of the intellectual force, which might have led to a true pathology of cancer of the uterus by fixing the attention upon structure, growth, and extension in relation to clinical phenomena. We have heard too much of cancer as neoplasm, too little of it as a disease If, now, we set aside all considerations of the etiology and pathology of cancer of the uterus and keep in mind only the clinical aspects of the disease, we see much ground for congratulation on the achievements of the last quarter of a century The clinical work has been wholly surgical. What is not surgical is futile—it is hardly knowledge.

What has been accomplished?—It is nearly 30 years since, as house surgeon to a gynæcologist of great local repute, I had every opportunity of observing the treatment of cancer of the uterus, a disease which when a student I had never once seen diagnosed by a clinical teacher The routine method was to clear away some of the débris of tissue from the invaded portion of the cervix and apply a liquid which had at the time a more general application in the treatment of certain diseases of the skin. The treatment was painful, and that was all No patient was kept in the hospital to die, and I need hardly say that no one received appreciable benefit. Next came the period of bromum and other specifics equally futile

A few years later I had the opportunity of witnessing the operations by the galvanic écraseur of the late Professor Carl Braun von Fernwald in the Vienna General Hospital He obtained a wonderful degree of success in arresting for years, and sometimes permanently, the progress of the disease by removing the vaginal portion of the uterus when that was the only part involved. Next Schroeder of Berlin practised and advocated the supra vaginal amputation of the cervix. The practice has been continued to the present time by some of Schroeder's pupils, notably by Hofmeier and Winter

Next came the period of progress with the operation of total extirpation. Many hesitated to attempt it owing to the immediate danger But the technique rapidly improved and it soon became the generally accepted operation, because it afforded the best grounds for hope of conferring prolonged benefit or of definitely curing the patient. Whatever we may think of the remote results of our surgical work no one who knows the history can deny that the reduction in the immediate mortality from this operation marks one of the greatest triumphs of modern surgery

Vaginal hysterectomy, when the disease is confined to the uterus, is not now more dangerous than is an ordinary ovariotomy The mortality, which at one time was over 30 per cent., has now sunk to 3 or 5 or 7 per cent., according to the extent of the disease and the concomitant complications or derangements of health. In recent years there has been a wave of mental depression passing over the gynæcological world on account of the unfavourable remote results of vaginal hysterectomy for cancer, and the most optimistic will admit that there has not been much ground for exultation. At a recent congress of American gynæcologists one of the eminent members said "There are *some men who claim for total extirpation of the uterus the* happiest results. Other men have looked upon the matter with utter hopelessness. I am sorry to say that I have brought myself among the latter class from bitter experience."[1] Hofmeier at the last Congress of German Gynæcologists declared that the present professional opinion and practice amounted to a declaration of "bankruptcy" of the radical vaginal operation as practised for the last 15 years. Of this statement Fritsch remarked "It has been said that we have gone bankrupt with our vaginal total extirpation, and that its place must be entirely occupied by the abdominal method, and this has been said about an operation from which better results have been obtained than from any other cancer operation whatever" But so far from the pessimistic view being *the true one the results obtained* by many of the best-known operators continue to improve and to give the greatest encouragement to continued efforts in the future. They are obtaining better immediate results and the number of "cures" increases—that is, the percentage of immunity for at least five years after operation becomes greater The percentage of cases operable when first seen also increases because the patients come earlier for treatment and improvements in technique have extended the indications The proof of all this lies in the statistics of carefully reported work done under circumstances in which the sources of error are reduced to the minimum. We may select examples from every country in Christendom, which now includes America, and the lessons taught by all are the same.

Von Ott *of St Petersburg gave the figures for Russia* in the Section of Gynæcology at Paris two years ago He mentioned 1000 cases of the radical vaginal operation, with a mortality of 10 per cent. for the work of many operators. Von Ott himself had performed 189 operations with a mortality of 1 6 per cent. For his own statistics he had experience of six years of freedom from recurrence, equal to 29 per cent. of cures, according to the conventional method of reckoning He had known cases of permanent immunity from recurrence which appeared to be hopeless before operation. Olshausen of Berlin operates now in 50 per cent of all cases, instead of in 31 per cent. as formerly Recurrence is not uncommon between three and seven years after operation, but very rare afterwards In 671 cases operated upon in the course of nine years the mortality was 6 per cent. In the last six years, between 3 and 4 per cent. In the last three years there were 291 cases with a mortality of 5 per cent. As to recurrence, over 36 per cent. of the cases were free after five years, after two years free from recurrence, 74 per cent, after three years, 62 6 per cent., after five years, 38 8 per cent. Zweifel of Leipsic now operates on 50 per cent. of all cases presenting themselves for treatment. Formerly he could operate on only 27 per cent. He considers the 27 per cent. of Leipsic a low figure compared with Berlin. Zweifel in the course of four years performed 219 vaginal operations with a mortality of 5 48 per cent Chrobak, in Vienna, operated in 213 cases with a mortality of 5 6 per cent. The proportion of operable cases increased *from 15 to 29 per cent* The percentage free from recurrence after five years was 34 6 In Schauta's clinic in Vienna 273 operations were performed The mortality for the vaginal operation was 10 per cent., for the abdominal operation 60 per cent. The mortality in uncomplicated cases operated on by the vaginal method was 4 6 per cent. Of these patients 36 per cent. were permanently cured When the cancer extended beyond the uterus the primary mortality was 23 per cent. and the permanent cures were 7 per cent Reipen gives the figures for Halle The operators were Kaltenbach and Fehling There were 303 cases and the operation mortality was 6 6 per cent. There was no recurrence within five years in 25 per cent. of the cases. In carcinoma of the body of the uterus alone there was no recurrence in 75 per cent. Cullen in America had no recurrence in 66 per cent. of cases of cancer of the body In 73 cases of cancer of the cervix he had 20 per cent. of non recurrence Kelly of Baltimore had had 63 per cent. of freedom from recurrence after six years in cancer of the body, in his cases of carcinoma of the cervix there was immunity from recurrence for from three to six years in 28 per cent. Kelly offers his testimony as to freedom of the pelvic glands from infection when the disease is confined to the uterus and therefore operable in the first degree. Hense gives remarkable evidence as to the influence of the climacteric in preserving from recurrence. In 73 cases of post-climacteric operation there was permanent freedom from recurrence in 50 per cent. Winter reports from Berlin 308 operations with a mortality of 50 per cent. Recurrence took place in nearly 70 within five years, and there were nearly 30 per cent of permanent cures Of the cases in which the operation could be effected in sound tissue the proportion of cures was 33 per cent. Winter remarks on the frequency of recurrence in the cicatrix. As representatives of Italy we may quote Spinelli and Mangiagalli The former reports 41 operations with a primary mortality of 2 4 per cent. but the 'cures" were only 8·9 per cent. Mangiagalli had 127 cases with a mortality of 8 6. Only 17 patients were free from recurrence after three years. In his cases recurrence was *always* in the cicatrix. In this country Lewers traced the history of 40 cases operated on radically per vaginam with a primary mortality of 7 per cent. There was freedom from recurrence in 27 5 per cent from two to seven years. In 11 cases of cancer of the body five of the patients were well from four to seven years after operation.

These illustrations of work done might be multiplied to an indefinite extent, but enough has been set down to support the statement that there is ground for encouragement, not for depression much less for despair in the recent history of vaginal hysterectomy for cancer Each story from which the bare figures have been culled contains its own lessons and its message of hope, encouraging us to persevere in the course on which we have entered. At the first glance there may appear to be but cold comfort in the figures, but we should remember that every woman cured" in even the conventional sense has been saved from a lingering and painful death. To our resources that will enhance the value of surgical interference in the future there has been in recent years no more valuable contribution than the improvement in technique introduced by the late Professor Schuchardt of Stettin. The most remarkable figures of all are those given by Schuchardt as the results of the paravaginal operation. The best results before were those of Leopold in Dresden, who with an operability of 20 4 per cent had 50 per cent. of conventional cures.' Schuchardt raised the operability to 61 per cent. and had conventional cures to the extent of 40 per cent. In easy cases he had the astonishing result of 80 per cent. of cures.

Reaction.—One of the results of the depression arising from the recognition of the unfavourable remote results of vaginal hysterectomy has been a rush, especially in Germany to the extreme verge of the practical in dissecting out not only the internal sexual organs but the whole of the lymphatics and cellular tissue of the pelvis. This has been declared to be justified by the belief that better remote results would be obtained than by vaginal hysterectomy

From a careful and laborious attempt to keep up with the record of proceedings I have no hesitation in saying that a large portion of the extended radical abdominal hysterectomies for cancer are homicidal vivisections which nothing hitherto advanced in their support appears to palliate, much less to justify Most of the cases recorded have been too far advanced for any operation however radical. The radical nature of these operations," says one German critic, is expressed only in the sad immediate and remote results, a high primary mortality and injuries to the ureters and bladder in those who survive for a time." The operators profess to dissect out the pelvic lymphatic glands iliac, hypogastric, sacral, inguinal, lumbar and they resect the ureters and reimplant them in the bladder when they interfere with the scope of their proceedings. The immediate mortality is terrific but then, as Jacobs said at *Amsterdam* the operation mortality is no longer an argument capable of arresting our efforts, and so far as experience of the remoter results has ripened for guiding inference all admit that the patients who escape with their lives from the operations occasionally reckoning only the possession of a permanent urinary fistula or the loss of a kidney among the consequences, are no better off in relation to recurrence than are those who have undergone the comparatively safe operation of radical vaginal extirpation.

THE FUTURE OF TREATMENT AND THE AIMS OF CLINICAL RESEARCH.

From all that has been said it must be obvious to those who care to listen to opinions of mine that I firmly believe the presently existing pessimism is not justified by the facts that there is much reason for encouragement to greater efforts in the future, and that our hopes must rest on early vaginal operation, not on the so-called extended radical abdominal sections. We may look forward to the future with a certain degree of confidence that considerable achievements are still before us even though the pathologists do not succeed in working out a theory of the causation with practical applications to therapeutics. In saying so I do not profess to assume the functions of the prophet. We can all enlighten the present on subjects which are the chief interest of our lives, and any real insight into the present is bound to shed some light on the immediate future by the ordinary process of cautious inference. Among the preliminary considerations which call for attention comes the question Is cancer of the uterus on the increase? My own firm conviction for a long time has been that it is not, in spite of all allegations to the contrary

The late Sir Spencer Wells in the Morton Lectures of 1888 gave rather an alarmist account of our prospects, but we must all welcome with a *sense of relief* the recent *statement* of Dr Tatham at the Chelsea Clinical Society According to Dr Tatham cancer in women is not increasing at the same rate as is cancer in men The increase in men and women respectively was in 1891–1900 as 147 to 74 There is not time to argue the matter out, but it seems reasonable to attribute the disparity of increase to a considerable diminution in the extent of cancer of the uterus and mamma. All this is especially reasuring when we remember that the disease is now almost always diagnosed at least in its later stages, whereas in former times it was in many cases overlooked even when it was about to produce, or had produced a fatal result. For example, if we keep in mind the cases in which there was little ulceration and much infiltration producing occlusions of the ureters and fatal uræmic convulsions, cases of early peritonitis and other complications, we must believe that the more general capacity for correct diagnosis has added considerably to the apparent increase of malignant disease in women.

If as I firmly believe, cancer of the cervix is a different disease from cancer of the body and is a *morbus miseriæ* like osteomalacia, leprosy and pellagra, it is bound to decrease as the social condition the physical well being the freedom from worries and the consequent comparative happiness of the people improve and become more general, if not universal.

Cancer of the cervix uteri occurs almost exclusively among the poor the chronically overworked and underfed—among poor prolific women, harassed, worried, drained by lactation, and reposeless. That fissures of the cervix neglected lacerations tissue changes in the cervix from flexions, irritations from venereal diseases remnants of puerperal sepsis affect the cervix I have myself no doubt whatever There is no time to argue the question, but each expression here used embodies an opinion and has the foundations of a thesis which I am prepared to maintain and defend. But we cannot afford to remain supine and inactive while the process of evolution is going on. We have seen disease eradicated in this country by social legislation—for example, mollities ossium, but no legislation that we can foresee will relieve our fellow countrywomen from the physical effects and the cares of large families, or save them from the consequences of their own negligence and from marital cruelty and selfish indulgences.

Our hopes of immediate amelioration rest therefore on surgery.—We must rely not on the extension of operative procedures into the brilliance of vivisections but on the united efforts of all concerned to bring the cases under surgical treatment at the earliest possible stage. We labour at present under considerable disabilities.

1. The patients are not so well trained and disciplined as German and other women in continental Europe. They naturally hesitate when they think of going to a medical man to tell of their symptoms and they neglect the most ominous symptoms with a light heart because they suffer no pain. The consequence is that as a rule our cancer patients consult the medical practitioner when it is clearly too late to do any operation justifying the hope of cure or even

prolonged immunity, and in many cases advice is sought for the first time only when it is almost too late to palliate.

2. This is clearly the most important of the many diseases regarding which the interests of the general practitioner in the subject and his influence with his patients are our chief ground for hope of ameliorations To him the patient first appeals and consequently on him depends whether steps shall be taken promptly or otherwise to bring the best resources of medical science to bear on the individual case. If I might venture a criticism, my own experience would suggest that all are not sufficiently insistent on physical examination even when there is *primâ facie* evidence that the cause of the symptoms is malignant disease. It is a painful fact and food for humble reflection that we still see presenting themselves at our hospitals poor women who have been under medical treatment for a considerable time without an examination being suggested to them, even although the first symptoms which they mention, and their age, and the appearance which they present should at once suggest the presence of cancer

3. Among the causes which lead to late diagnoses of malignant disease of the uterus—partly by leading the patients to present themselves late and partly to the postponement of examination—is the prevalent superstition with regard to a "climacteric hæmorrhage." I have no hesitation in saying with entire conviction that "climacteric hæmorrhage" is, like the collective term "cancer," one of the inherited burdens which we drag along with us to our hindrance and grievous detriment Apart from pathological conditions usually diagnosable there is no such phenomenon in nature.

4 Another popular delusion which stands in the way of early diagnosis of cancer of the uterus is the belief that pain is an invariable symptom of cancer When the sufferer from cancer begins to complain of pain we all know now that the disease is too far advanced for radical treatment. The question naturally arises, How is this universal ignorance to be dissipated? If our patients only knew what symptoms were suspicious the fear of death would overcome the natural shrinking from examination and the medical adviser would be taken early into confidence.

The nature of the subject precludes popularising of knowledge by ordinary methods, but a great deal more might be done by the means now available. Dr Lewers makes a helpful suggestion in the *Practitioner* for June that a cancer research commission might be the agency of diffusing knowledge of the subject through nurses, district visitors, sanitary associations, and others who come into intimate relations with the more ignorant and poorer classes of the community

As far as the medical profession is concerned the chief difficulty in the way of obtaining better results by early operation is that of early diagnosis. Anyone engaged in the practice of the medical profession should have no difficulty in diagnosing cancer of the uterus when a cavity has formed or the patient is suffering from one of the hypertrophic forms of epithelioma of the cervix But there are cases in which there is real difficulty in establishing early diagnosis of uterine cancer Now it is mere mockery and the suggestion of utter impracticability to tell a busy medical practitioner to snip bits off the affected part and to subject them to microscopic examination. The busiest men see the most cases and therefore are least able to follow the advice. There are the various clinical research societies, of the assistance of which a small minority take advantage, but they cannot be expected to supply the wants of the whole profession like a clinical test of easy application

And then we must keep in mind that it is easy to place too great reliance on mere microscopic diagnosis. It is, for example, impossible to diagnose between benign adenoma of the corpus uteri and the malignant form of the disease by means of the microscope alone, the distinction is purely clinical And those who hold strongly, as I do, that the finer clinical points are constantly overlooked because of the air of scientific accuracy which the masters of the microtome assume will not readily forget the history of the discussion on the claims of the total extirpation of the uterus as against any partial operation. Certain young "gynæcologist-pathologists" in Germany at one time discovered that in carcinoma of the cervix the mucosa of the body of the uterus underwent a sarcomatous degeneration, and as usual they published their observations to all the world. Immediately the same curious phenomenon, *a priori* improbable as it was, was observed in every *Frauenklinik* in Germany, and the scientific proof of the futility of partial extirpation was established! We never hear of that sarcomatous degeneration now, for it was soon proved beyond cavil to be the result of a purely inflammatory process Syphilitic tumours have been described as microscopically indistinguishable from large-celled sarcoma, and tuberculous growths have also been mistaken for malignant disease

How then can early diagnosis of carcinoma of the cervix be established clinically? I would once more suggest the value of friability of tissue as pathognomonic in this particular phase of malignant growth. The presence of friable tissue in the cervix uteri indicates the existence of disease which is clinically malignant whatever the microscope may say

With goodwill and general interest in the subject and by early diagnosis it should not be difficult to bring the proportion of operable cases seen in this country to something approaching that of Germany Success even so far would mean the saving of many lives and a great reduction in the amount of human misery What the proportion of operable to inoperable cases of cancer of the uterus when first seen in this country generally may be we do not clearly know I do not think there have been sufficient observations published to enable us to form a conclusion. At the Southern Hospital here a careful inquiry into the figures of the last 10 years made by the present house surgeon, Dr A. M. Mitchell, shows the proportion to be about 22 per cent Dr Munro Kerr has been kind enough to make inquiries with regard to the subject in Glasgow and he tells me that out of 118 consecutive cases seen at the Western Infirmary there were 98 found to be inoperable—that is to say, 18 per cent. of operable cases At our Christie Hospital here operable cases are seldom seen, but the circumstances are exceptional and palliation must be the recognised treatment German gynæcologists have succeeded in raising the proportion of operable cases from as low as the figures I have just quoted to over 20, over 30, and now in some clinics, such as Olshausen's, to 50 per cent., and Schuchardt reached the extraordinary figure of 61 per cent. With such examples before us it would surely be criminal folly to despair of equal or greater progress among ourselves And, indeed, suggestive and encouraging signs are not wanting of aroused attention and interest in the promptness with which cases are now being submitted to operation compared with even the recent past.

What has been implied in all that I have said I now wish to state explicitly for what it is worth. It is my firm conviction that the secret of cancer in general will be discovered, if ever, by the study of carcinoma of the uterus, and that the means will be exact clinical observation, followed, perhaps, and corroborated, by experimental research

The microtome and the cultivation tube and experimental implanation have had their day, they need not cease to be, but they should find their proper place in our system of investigation. We may get at the causes of malignant disease, as far as we understand the causes of things, by exact clinical observation, but the specific remedy or the system of therapeutics will come, in all probability, as a stroke of empiricism from an individual working for the sake of knowledge and for the good of humanity It might be argued that the pathology and serum treatment of tuberculous disease and diphtheria are examples to the contrary, but there appears to be hardly any analogy between the genuinely infectious diseases and the phenomena of cancer

Cancer is infectious to the individual already affected with cancer, but to no other The phenomena of rapid recurrence in the cicatrix after operation, owing to contact of the fresh wound with cancerous matter, points to an early cancerous condition of the system, an entirely different matter from the late cancerous cachexia. This fact, established clinically, has received too little notice

APPLICATION OF LOGICAL METHODS

If we are ever to arrive at the causation of carcinoma of the uterus we must reach it by the rigid application of logical methods of induction to clinical work. We are already in possession of certain facts established clinically with regard to cancer of the body and cancer of the cervix and the extent to which they are dissimilar We might begin our collective investigations with carcinoma of the cervix. It is a diseased condition with antecedents and characteristics almost entirely its own. Its characters fit it specially for clinical observation and the application of logical methods of induction

"If two or more instances of a phenomenon under investigation have only one circumstance in common that circumstance *is the cause of the phenomenon.*" The application of this Method of Agreement would require very patient note taking according to a rubric containing every antecedent circumstance which has ever been suggested as the cause or connected with the cause of the disease. But genius is the faculty of taking infinite pains. After a time it would be seen what was the invariable antecedent, if any in every case. If there was no invariable antecedent of the phenomena of the disease over a considerable series of cases, then the rubric would have to be strengthened by new possible antecedents, while the obviously irrelevant could be abandoned. By the antecedent circumstances I mean such facts as heredity previous illnesses especially contagious diseases, social circumstances, marriage child bearing puerperal ailments lactation, menstruation and an indefinite variety of others. One of the earliest results of this method would probably be the differentiation of the varieties of malignant disease of the uterus just as clinical work alone established the differences between the fevers in the past. We would learn which clinical varieties produced early lymphatic invasion, which most readily recurred where the recurrences commenced and how the last state of the operation case after recurrence compared with the case in which the disease had been allowed to run its course unaffected by treatment. Facts would be proved, fables dissipated. Conclusions formed would become opinions, not mere individual impressions.

CONCLUSION

Running through all I have said and implied in some apparent digressions has been an effort to attract attention (as far as anything I may say can do so) to the dignity and the effectiveness of exact scientific clinical methods of observation. To attain my object it seemed necessary to call specific attention to the futility of much of the labours of the past undertaken in order to establish the etiology and true pathology of cancer All honest and enlightened human effort should be welcomed I depreciate none. But chiefly is my hope fixed on the fact that in such research as I have been suggesting every member of the medical profession engaged in general practice could coöperate in genuinely scientific work with those whose daily occupation was of a special character The work of both sets of workers would be complementary The specialists should have more time as a rule to devote to such work and naturally they have the particular disease more in their minds The medical practitioner knows most about the history and environment of the individual patient and can obtain relevant information from which the hospital physician is excluded.

I shall not parody the language of the great German authority upon whom I have so largely drawn and speak of a Promised Land I shall content myself with saying that my earnest hope and desire is this—that some of our younger men, with more energy better opportunities starting on a higher level of knowledge, will professedly take up this great enterprise and see whether by calm, industrious, and enlightened clinical observation alone or collectively they can discover the cause and the remedy for this mysterious and dreadful malady

CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

(Concluded from p 280)

THE cases which I have referred to have supplied illustrations of the effect of treatment in carrying the condition back from the double to the simple form Looking at all the circumstances before us it is only reasonable to expect that the abnormality induced by the constant passage of sugar in large quantity through the system is likely to favour the progress of the disease into the more advanced form and conversely that the removal or diminution of the abnormality is likely to *exert an* influence *tending to operate* in an opposite direction. In the cases which I have considered we have started with the presence of the acetone series and have seen the result that may follow I will now pass to the consideration of cases in which the products in question have been absent before beginning the treatment and show the result *that may attend the transition from a diet* containing carbohydrate to one from which it is excluded.

The usual effect, I think I may say, that may be looked for is that a certain amount of the products is thrown into the urine The amount, however, is not what can be called large and with the progress of time it tends to grow gradually less and finally to disappear In young subjects the products seem to hold on more tenaciously than in subjects of more advanced years The following may be given as illustrative cases.

CASE 8.—This was a male patient, aged 47 years At his first visit on Sept. 17th 1901 the report ran Sugar 62 per 1000 and diacetic acid 0 On Sept. 20th, as a result of the restricted diet the sugar had become reduced to 22 per 1000 and the diacetic acid had appeared to the extent of ++ Oct. 4th Sugar, trace , and diacetic acid 0

CASE 9 —This patient, aged 51 years, had been the subject of diabetes for four and a half years. He had just arrived from India and latterly from the difficulty in dieting whilst travelling had not been giving the attention to food that he had done formerly He was first seen on May 23rd, 1902, when the sugar stood at 83 per 1000 and diacetic acid 0 May 26th Sugar 20 per 1000 diacetic acid + and acetone, + 28th Sugar 13 per 1000 , diacetic acid, + and acetone + June 11th Sugar 10 per 1000 and diacetic acid 0 24th Sugar 6 per 1000 diacetic acid 0 and acetone, 0 July 8th Sugar trace diacetic acid 0 and acetone, 0 July 22nd Sugar 0 , diacetic acid 0 and acetone, 0

CASE 10 —The patient, aged 56 years, had recently become the subject of diabetes. June 21st, 1902 Sugar 55 per 1000 and diacetic acid, 0. 23rd Sugar 10 per 1000 diacetic acid, + and acetone, + 25th Sugar 0, diacetic acid, + and acetone, + July 5th Sugar 0, diacetic acid + and acetone, ++ 10th Sugar, 0, diacetic acid + and acetone, + 22nd Sugar 0, diacetic acid, 0 and acetone, +

CASE 11.—In this case diabetes had existed for five months. The patient was 55 years of age and was first seen by me on June 15th, 1900 He was at the time upon a partially restricted diet and the sugar stood at 29 per 1000 and diacetic acid, 0. July 6th Sugar 0 and diacetic acid, + August 17th Sugar 0 and diacetic acid 0.

CASE 12.—The patient, aged 64 years was first seen on March 7th, 1902. Sugar had been recognised in his urine in 1896. He latterly had been relaxing his diet. Marked neuritis existed. Sugar 27 per 1000 and diacetic acid, 0 March 27th Sugar 10 per 1000 and diacetic acid + June 6th Sugar 0 , and diacetic acid 0

The following two cases are of boys in the urine of whom a persistence is shown of the acetone products, notwithstanding the absence of sugar for a considerable time. It is not to be taken that it invariably happens with children in this way

CASE 13.—The patient, aged eight years was first seen on Nov 15th 1899 A sharp onset of thirst had occurred eight days previously and sugar in the urine had just been recognised. Sugar by copper reduction, 77 7 per 1000 , by polarimeter 77 3 per 1000 diacetic acid + , and albumin, 0 The disease had only just set in and the presence of sugar was almost the only abnormality presented by the urine. There was no oxybutyric acid and only a little diacetic acid The patient was placed immediately on the strict diet and for Dec. 7th the report runs as follows Sugar by copper reduction 0 polarimetric indication expressed in terms of dextrose − 4 6 per 1000 and diacetic acid +++ Thus a levorotatory power to the extent named now existed and there was a large quantity of diacetic acid On Jan. 4th 1900 the report ran almost the same Sugar 0 polarimeter − 4 3 per 1000 and diacetic acid, +++ The boy had risen in weight from four stones and four and a half pounds to four stones and 10½ pounds between Dec. 7th and Jan. 4th. On March 1st the report was practically the same. On the 22nd with a continued absence of sugar the levorotation had become reduced to −2 1 per 1000 and the diacetic acid to ++ June 27th Sugar 0 polarimeter −2 9 per 1000 and diacetic acid + Oct. 4th Sugar 0 polarimeter, −1 7 per 1000 and diacetic acid + Dec. 19th Sugar 0 polarimeter 1 4 per 1000 and diacetic acid, + Feb. 15th, 1901 Sugar, 0, polarimeter, −1 8 per 1000, and diacetic acid, 0 This constituted the maximum of improvement attained and from this time retrogression occurred For March 12th the report ran Sugar, by copper reduction, 37 per 1000, by polarimeter, 28 per 1000, and diacetic acid, ++ A loss of one pound in weight had taken place during the last week June 4th Sugar, by copper reduction, 46 per 1000, by polarimeter, 32 per 1000, and diacetic acid, +++ The patient now rapidly lost ground and died in a comatose state in September

CASE 14 —This patient was also eight years of age when first seen on Jan 25th, 1902. He was of an exceedingly high strung nerve organisation Some increased flow of urine had been noticed at the end of November, but the condition afterwards fluctuated and it was not until the middle of January that it received serious attention From this time urgent thirst, polyuria, and emaciation attended with weakness set in The examination of the urine on the 25th revealed the following condition Sugar, by copper reduction 71 per 1000, by polarimeter 60 per 1000, diacetic acid, +++, and acetone, ++ The patient was put upon the restricted diet with the exception of the allowance for a few days only of about a pint of ordinary, instead of sugar free, milk per diem Jan 30th Sugar, by copper reduction, 59 per 1000, by polarimeter, 46 per 1000, diacetic acid, +++, and acetone ++ Feb 6th Sugar, by copper reduction, 46 per 1000, by polarimeter, 36 per 1000, diacetic acid, +++, and acetone, ++ 13th Sugar, by copper reduction, 26 per 1000, by polarimeter, 23 per 1000, diacetic acid, +, and acetone, + The weight last September was four stones and two pounds, on Jan 23rd it had fallen to three stones and six pounds, on Feb 6th it was three stones and 10 pounds, on the 7th three stones and 10½ pounds, and on the 13th three stones and 11¾ pounds Feb 20th Sugar, 0, diacetic acid, +, and acetone, + 27th Sugar 0, polarimeter, −0·6 per 1000, diacetic acid +, and acetone, + On the 23rd the patient had a bad attack of sickness from which he had since recovered March 6th Sugar, 0, polarimeter, −1 6 per 1000, diacetic acid, ++, and acetone, + The patient's weight on this date was three stones and 13¾ pounds March 20th Sugar, 0, polarimeter, −1 8 per 1000, diacetic acid, +, and acetone + April 10th Sugar, 0, polarimeter, −5 7 per 1000, diacetic acid ++, and acetone ++ May 8th Sugar, 0, polarimeter, −3·6 per 1000, diacetic acid ++, and acetone ++ The weight of the patient had reached four stones and four pounds On May 26th it was found that the patient had contracted whooping cough and he had lost one and a half pounds in weight. Sugar 0, polarimeter, − 3 9 per 1000, diacetic acid + +, and acetone, + + On June 24th the whooping cough was better The loss of weight, which on June 11th amounted to three pounds, was now being recovered, and the weight stood at four stones and two pounds Sugar, 0, polarimeter, − 4 3 per 1000, diacetic acid, + +, and acetone, + + The last entry is for July 24th and stands as follows Sugar, 0, polarimeter, − 1 5 per 1000, diacetic acid, 0, and acetone, +

In the above case a riotous upset of metabolism had occurred The chemistry of life had fallen into a highly perverted order of procedure By bringing the system into a more natural state through the removal of the sugar things have for the time almost righted themselves and health so far has become re established, the boy to outward appearances being as well as at any time in his life The age, however, is the baneful point on giving heed to the future.

In opposition to the effect of restriction from carbohydrate food that has been noted, cases are frequently occurring in which the sugar disappears without evidence being presented of the products of the acetone series being developed One example of this line of case will suffice for illustration.

CASE 15 —The patient, aged 58 years, was first seen on June 24th, 1902 Sugar had been recognised in his urine four years previously Latterly his symptoms had grown worse and he had become anxious about himself. He was on a partially restricted diet, partaking of starchy food under the form of brown bread and toast. His urine contained 50 per 1000 of sugar and gave no reaction with the ferric chloride test for diacetic acid. On June 28th, four days after commencing the restricted diet, the sugar had become reduced to 13 per 1000 and diacetic acid was absent. July 5th Sugar, 5 per 1000, and diacetic acid, 0 12th Sugar trace, and diacetic acid, 0 26th Sugar, trace, and diacetic acid, 0

The acetone series may become present in the urine of the diabetic as a result of the supervention of some other disorder and subsequently disappear The following three cases represent instances of the kind

CASE 16 —Pneumonia was in this case the disorder that supervened The patient first came under my observation in February, 1899 She was then 60 years of age At the first interview the sugar amounted to 55 per 1000, but under treatment it soon disappeared, and later six ounces of ordinary bread per diem could be taken without leading to the passage of sugar The urine gave no reaction with the ferric chloride test for diacetic acid In the early part of November, 1900, the patient took a chill which resulted in the development of pneumonia. On Nov 10th the condition of the urine was as follows Sugar by copper reduction and by polarimeter, 33 per 1000, diacetic acid, +, and a trace of albumin and granular and hyaline tube casts. 12th Sugar by copper reduction, 48 per 1000, by polarimeter, 39 per 1000, and diacetic acid, ++ 13th Sugar by copper reduction, 43 per 1000, by polarimeter, 36 per 1000, and diacetic acid, +++ 14th Sugar by copper reduction, 27 per 1000, by polarimeter, 21 per 1000, and diacetic acid, ++ 15th Sugar by copper reduction, 21 per 1000, by polarimeter, 19 per 1000, and diacetic acid, + 16th Sugar by copper reduction, 15 per 1000, by polarimeter, 12 per 1000, and diacetic acid + From Nov 30th there was a disappearance of diacetic acid, but a slight amount of sugar with a trace of albumin and casts persisted till March, 1901 On April 18th the report ran Sugar, 0, diacetic acid, 0, albumin, 0, and no casts The patient has since continued in a satisfactory state and has regained her former tolerating capacity for six ounces of ordinary bread per diem She was last seen on July 11th, 1902.

CASE 17 —In this case excess of alcohol and dietetic deviation were at the foundation of the "composite" condition that became developed. My history of the patient begins with April, 1893 He was then 39 years of age. There was a strong family history of the disease and, as often happens in these circumstances, the diabetes commenced in a mild form and was, indeed, first recognised through examination for life assurance For a considerable time there was only a certain amount of impairment of assimilative power over carbohydrate In 1897 a curtailment of the carbohydrate previously taken was required to keep the urine free from sugar In 1900, through dietetic deviation, sugar was sometimes present in considerable amount and diacetic acid began to show itself Whisky was also being taken to a pernicious extent. The condition of the urine on Oct 4th, 1900, stood as follows Sugar by copper reduction, 25 per 1000, by polarimeter, 17 per 1000, and diacetic acid + March 13th, 1901 Sugar by copper reduction, 32 per 1000, by polarimeter, 25 per 1000, and diacetic acid, + On Oct 4th the patient was in a thoroughly disordered state He was feeling ill and losing weight. His liver was to be felt three inches below the margins of the ribs and his urine contained albumin with hyaline and granular casts Sugar, 41 per 1000, and diacetic acid, ++ Alarmed about his condition he almost abstained from whisky and resumed the proper dietary for his disease Nov 27th Sugar 0, and diacetic acid, 0 Jan 10th, 1902 Sugar, 0, diacetic acid, 0, albumin, 0, and no casts Up to May 9th the reports continued to be good When seen on July 4th he had relapsed into his former mode of life with a return to his previous condition. The report upon his urine was as follows Sugar by copper reduction, 56 per 1000, by polarimeter, 54 per 1000, diacetic acid, ++, and albumin and granular casts were present.

CASE 18 —This was a case of diacetic acid following a severe attack of sciatica. The patient had been under treatment for diabetes since February, 1895, when she was 57 years of age. At first it was not difficult to keep the urine free from sugar under the allowance of a moderate quantity of starchy food in the form of bread. Latterly less toleration of bread had existed and the amount of sugar, from insufficient restriction being exercised, had grown to an undesirable extent When the patient was seen in July, 1901, there was, as previously an absence of diacetic acid At the beginning of October she took a chill from walking in thin shoes on damp grass and contracted a severe attack of sciatica For several nights she was unable to remain through the night in bed and had to rest in a chair She was convalescing when I saw her on Oct 22nd. The urine then contained 50 per 1000 of sugar with diacetic acid represented by +++ On Nov 27th the diacetic acid had disappeared and its absence has since been noted at interviews on Jan. 23rd April 14th and July 20th of the present year

The passage into the composite" state thus supervening upon the development of another disordered condition may rapidly run on to the production of coma The following is a case in point.

CASE 19 —The patient was first seen in March 1898, when she was 67 years of age The absence of sugar was easily susceptible of being maintained by limitation of starchy food There had never been any indication of the presence of diacetic acid and on Sept. 20th, 1901 its absence was noted. In November the patient took cold and became the subject of bronchial trouble and of a severe attack of muscular rheumatism affecting the back of the neck and shoulders and giving rise to an extreme amount of distress. On Dec. 2nd the urine contained 31 per 1000 of sugar diacetic acid corresponding with +++ and acetone ++ On Dec. 9th the following condition was found Sugar by copper reduction 45 per 1000 by polarimeter 38 per 1000, diacetic acid +++ and acetone, + a trace of albumin was also present with the distinctive casts associated with diabetic coma. The patient died in a comatose state on the following day

In the cases that have been alluded to the composite state has arisen with the occurrence of a supervening malady If the composite state should already exist the supervention of another malady upon it is attended with the greatest danger and thus the insecure tenure of life known to be associated with advanced diabetes is in part to be accounted for The following is an illustrative case

CASE 20 —The patient first fell under my notice in June 1901. He was then 53 years of age and had been for many years the subject of diabetes Sugar was found to the extent of 21 per 1000 and a certain amount of diacetic acid was present I was asked to see him on March 3rd 1902. He had just arrived from abroad and had contracted influenza from the inmates of the house at which he was staying The examination of his urine revealed the following condition Sugar by copper reduction 41 per 1000, by polarimeter 30 per 1000 diacetic acid +++ acetone +, and albumin in decided amount accompanied with numerous casts Two days later the patient died in a comatose state.

The information given by the acetone series is of much prognostic value. Indeed, the knowledge they supply in connexion with a case furnishes an insight into the future which cannot be obtained by looking solely to the sugar Sufficient already has been said to show that it is not to be concluded that their presence is indicative of imminent fatality but at the same time their presence to a pronounced extent and without any outside influence to account for them must be regarded as of exceedingly bad augury Weintraud[1] states that he noticed the presence of diacetic acid in one of Naunyn s cases five years before death occurred. I may in connexion with this matter cite from my own experience the following case.

CASE 21 —The patient was first seen in September 1885 He was then 48 years of age. After progressing in a fairly satisfactory manner till December 1899 diacetic acid then showed itself in his urine. The report ran Sugar by copper reduction, 22 per 1000 by polarimeter 22 per 1000 and diacetic acid + On April 5th, 1900 the following condition was found Sugar by copper reduction, 34 per 1000 by polarimeter 28 per 1000 and diacetic acid ++ My next record is for Nov 1st, 1901, when the report stood Sugar by copper reduction, 34 per 1000, by polarimeter 33 per 1000 and diacetic acid + I have not seen the patient since, and as far as I am aware he is still alive.

When the acetone series of products are discoverable to a large extent in a case it may be safely concluded that life is not likely to last long On March 5th of this year a patient came to me bringing urine that yielded on examination the following results Sugar by copper reduction, 61 per 1000 by polarimeter 37 per 1000 and diacetic acid, +++ I felt that the patient could not in this condition last long and I wrote accordingly to the local medical attendant. She died in coma 12 days after The difference between copper reduction and polarimeter values here amounted to 24 per 1000 These are about the highest figures I have met with, and when brought into terms of actual oxybutyric acid give 53 per 1000 as the quantity present.

The following case also affords a good illustration of the value of the information derivable from a detailed examination of the urine for the acetone series

CASE 22.—The patient, aged 38 years, first fell under my observation on April 14th 1902. He had noticed in the previous autumn from his Turkish bath weighings that he was steadily losing weight and through this he sought advice when the existence of diabetes was recognised. There had been no urgent thirst or great flow of urine and the condition had not been regarded as one to call for immediate anxiety A partially restricted diet was being followed. The full examination of the urine showed at once the grave state existing The following were the results obtained Sugar by copper reduction, 50 per 1000, by polarimeter 39 per 1000 diacetic acid +++ acetone, ++, and a trace of albumin with granular and hyaline casts Several subsequent examinations were made which showed some fall in the sugar but the acetone series persisted to about the same extent and the patient grew gradually worse till July 9th when death took place.

The testing for diacetic acid is a matter of easy accomplishment and it gives a certain amount of information, but the value of the information conveyed is not to be compared to that obtained from the quantitative determination of the oxybutyric acid by the agency of copper reduction and the polarimeter This, however requires experience and time, but the result may be considered to repay the labour undertaken A double process is involved. It is possible, however by fermenting away the sugar to make the polarimeter alone serve for giving the required information. If this is done confidence has to be placed in oxybutyric acid possessing the power of fully resisting destruction during fermentation, which is doubtful

Grosvenor-street, W

MYOMA OF THE VAGINA

BY W ROGER WILLIAMS F R.C.S ENG

CANCER of the vagina is rare sarcoma is rarer still, and myomatous tumours are the rarest of all. Although the vaginal musculature is much thinner than is that of the uterus in other respects there is much similarity between them except that the former lacks the post-embryonic developmental potentiality of the latter It is owing to this functional difference, and consequent diversity in the number and arrangement of its blood vessels &c. that myomatous tumours arise so very much less frequently from the vaginal than from the uterine walls. The musculature occupies an intermediate position in the vaginal parietes, between the corium of the mucosa" and the fibrous tissue of its outer coat, to both of which it sends processes. It is most abundant in the lower part of the vagina, especially anteriorly in the vicinity of the base of the bladder, and it is significant that these are just the localities where vaginal myomata are most prone to develop Blood-vessels lymphatics and nerves also enter into its composition.

As in the case of their uterine congeners the precise structure of vaginal fibroids" has been much debated and as Virchow long ago remarked, the reports of cases rarely enable us to determine with certainty whether we have to do with myomatous fibro-myomatous or merely with fibromatous formations To a certain extent this criticism is still valid. No doubt the relative proportions in which myomatous and fibrous structures enter into their formation is very variable but, in spite of difficulties of this kind—and the rarity with which observers have resorted to the special reagents and technique necessary for the discrimination of leiomyomatous elements—it appears that the great majority of recently recorded cases have been myomatous. This was obviously so in 19 of the 29 modern cases tabulated by Phillips Probably future investigation will show that nearly all vaginal fibroids" are myomatous *ab origine*

Vaginal fibroids differ from their uterine congeners in their comparative rarity (only three to 1073 cases) and in that they are nearly always solitary Instances of multiple vaginal myomata have however been reported by Odenin and Strassmann Odenin s patient was a peasant, aged 32 years who when only 18 years old had twins and subsequently one miscarriage At several sittings no less than 10 myomatous tumours were removed from the vaginal walls

---

[1] Archiv für experimentelle Pathologie und Pharmakologie Band xxxiv

These tumours were of variable sizes—the largest being as big as the fist, two others were of the size of hen's eggs, and the rest were smaller Some of the tumours were stalked, others were sessile. They were circumscribed, hard, lobulated, and whitish on section Histologically examined their structure was that of "myoma lævicellulare." In Strassmann's case two small, partially calcified, tumours were present. Leisering has met with over 20 tumours of this kind in the walls of the vagina of a dog In cases reported by Stumpf and Strassmann the tumours were multinodular Hastenpflug, Byford, Oliver, and Taubert have found tumours of this kind coexisting in the vagina and uterus Schroeder and Pillore have met with the like concurrence in the vagina and ovary, while Virchow has described an instance in which the vagina, the uterus, and the ovary were concurrently affected. An instance of vaginal myoma in an unmarried woman, 21 years old, who was the subject of double uterus and vagina, has been reported by Emmet. Most vaginal fibroids are of intra peritoneal origin, springing from the musculature, but exceptionally they arise in neighbouring tissues (paravaginal) Aberrant uterine myomata, sequestrated from their original matrix, sometimes acquire a paravaginal *habitat* The great majority of vaginal myomata originate anteriorly, this was the condition in 25 of Kleinwächter's 39 cases and in 23 of Phillips's 29 cases Veit believes that many myomata originate in connexion with Wolffian "rests" In support of this view Pick has described a remarkable myomatous tumour of the posterior vaginal fornix which contained epithelial lined tubules similar to those found by Recklinghausen in uterine myomata. Krönig and Poupinel have also met with structures of this kind in tumours of this vicinity At an early stage of development the vaginal "fibroid" presents as a small, hard, circumscribed, mobile tumour in the vaginal wall As it increases in size it usually tends to project into the vagina, being covered by its muco-cutaneous lining membrane. The tumour is at first sessile and it may continue so, but more commonly it gets involved in the vaginal lumen and so acquires a pedicle which is generally short and thick. Sometimes, however, the pedicle undergoes such elongation as to admit of the "fibroid" hanging from the vulva, and large tumours have been known to reach even as low as the knees, of which Paget has cited instances The implantation area of large tumours is generally well supplied with blood vessels, which may bleed freely when divided.

Vaginal "fibroids" increase slowly, several cases of over 12 years' duration having been reported, but they seldom attain large size. When first noticed they are commonly no bigger than a hazel nut or a walnut, but specimens of the size of a child's head and weighing over 10 pounds have been met with. Large tumours cause great distension of the vagina and by their bulk interfere with the functions of adjacent organs, such as the bladder, the rectum, &c These large tumours constitute a serious malady, but the small ones seldom cause any special inconvenience Extruding tumours are apt to be complicated by inversion of the vagina, and in displacements of this kind the bladder or rectum may be involved. Such tumours may even separate spontaneously and be expelled per vaginam, of which several instances have been reported. In their morphological characters vaginal myomata resemble their uterine congeners, as they are generally encapsuled, circumscribed, nodulated, and of dense quasi fibrous texture Softish varieties are, however, met with which may be telangiectasic or lymphangiectasic, as in cases reported by Boutin, Hofmokol, Flunderberg, and others. Calcification is rare, but instances have been reported by Taubert and Strassmann

By far the commonest of the superinduced changes met with in these tumours are those that result from *septic infection*—viz , congestion, œdema, inflammation, necrosis, and gangrene, which are usually consequent on some form of injury Salpingitis, pyosalpinx, peritonitis, and septicæmia are frequent concomitants of this kind of accident.

Any form of malignant disease originating in vaginal myomata is most exceptional, but sarcomatous changes have been reported by Homs and Cartlege, and myxomatous by Kleinwächter and Péan. With regard to the age incidence of 20 cases tabulated by me the youngest—when the first indications of the affection were noted—was 20 years and the oldest 46 years, and their mean age was 33 4 years When these same patients sought surgical advice owing to the supervention of more or less urgent symptoms their average age was 34 6 years Thus vaginal myomata occur on the average several years earlier than do their uterine congeners The age distribution of these 20 patients at the onset of the disease was as follows from 20 to 30 years in six cases, from 30 to 40 years in nine cases, from 40 to 45 years in three cases, and from 45 to 50 years in two cases This shows a preponderance of cases arising during the fourth decade—i e , prior to the menopause R. R. Smith's analysis of 69 recently reported cases agrees with this, for 40 5 per cent of his patients belong to the fourth decade According to Kleinwächter, however, the period of maximum liability is considerably later—viz., at about the time of the menopause. It is alleged that these tumours may be congenital or appear during early infancy, but anyone who cares to study the reports of the cases commonly cited in support of this statement—viz., those of Martin, Traetzl, and Wilson—will see, as I have elsewhere pointed out,[1] that none of the polypoid formations in these cases were really of the nature of myomata. A considerable proportion of those affected with these tumours are single and among the married the ratio of sterility is in excess of the normal. Vaginal "fibroids," even when of some size, seldom cause menorrhagia or other menstrual derangement, for of R. R. Smith's 69 cases menorrhagia was noted only in seven. Irregular hæmorrhagic vaginal discharges are occasionally met with (15 times in 101 of R. R. Smith's cases) The liability to conception is but little affected, hence the tumours are often concomitant with pregnancy, and instances of dystocia from this cause have been reported (Pelletan, Gensoul, McClintock, and others) In McClintock's case the tumour was gangrenous The projection of the tumour at the vaginal orifice is usually the first indication of the disease, and it is for this rather than for special symptoms caused by the tumour that most patients first seek professional advice Painful and difficult micturition, with blood-stained urine in some cases, are among the early symptoms, and at a later period there may be retention of urine, but this is rare except with large tumours Difficulty in defecation may also occur but severe obstruction is very exceptional. Leucorrhœal discharge, painful coitus, lumbo-sacral pain, and sanious discharge are also among the initial symptoms occasionally observed. At a late period the surgeon is often consulted on account of inflammation and necrosis of the tumour as well as for its troublesome bulkiness

In making the diagnosis of vaginal tumours it is well to recollect that this part of the body is prone to originate localised invaginations and prolapses (cystocele, rectocele, enterocele, &c) which at first sight often present a certain resemblance to myomatous and other tumours, cysts, &c. In displacements of this sort the bladder and urethra are often involved while the rectum generally escapes Vaginal displacements are especially apt to occur during labour complicated by the presence of vaginal tumours. Cysts of the part, especially when circumscribed, thick-walled, and tense, may closely simulate vaginal myoma. Usually, however, vaginal myomata are easily diagnosed. Myomata of any size, especially when they interfere with natural functions or present signs of septic infection—inflammation, œdema, sloughing, &c —should be removed. Similar treatment is required for tumours that have been extruded from the vulva or that obstruct the vaginal outlet. Aseptic technique should be observed.

In dealing with polypoid tumours if the pedicle is of no great thickness, and accessible, it should be transfixed, ligatured in two places, and divided between the ligatures. Before effecting division it is well to ascertain that no diverticulum of the vagina, bladder, or rectum is involved in the pedicle In all other cases enucleation is the best method of treatment The bladder and rectum having been evacuated the vaginal walls are separated by retractors and the tumour is seized with the toothed volsella and brought into view Should it be very large and the vagina narrow vaginal *débridement* may be necessary For anteriorly situated tumours the catheter is retained in the bladder to guard against injury of the urinary tract, while a deep and free incision is made into the presenting part of the tumour, laying open its capsule. With the handle of the scalpel, an enucleator, or other suitable blunt instrument the tumour is gradually separated from its bed and removed To effect this with large tumours morcellation may be necessary During the enucleation of posteriorly situated tumours a guiding finger or bougie should be kept in the rectum The hæmorrhage attending the removal of vaginal myomata is often free. Bleeding points should be seized with pressure forceps and ligatured The redundant margins of the tumour bed having been resected deep sutures are passed with a handled needle so as to close the gap and at the same time to surround and compress the bleeding areas. The closure of the wound is then completed with superficial sutures. Finally the vagina is lightly packed with iodoform gauze. In exceptional cases it may be necessary for the arrest of hæmorrhage to gauze pack the bed of the tumour Tumours of this kind concomitant with pregnancy should not be interfered with unless they seem likely to cause dystocia or unless they have become septically infected sloughy &c. when they should be promptly removed, the pregnant uterus being interfered with as little as possible.

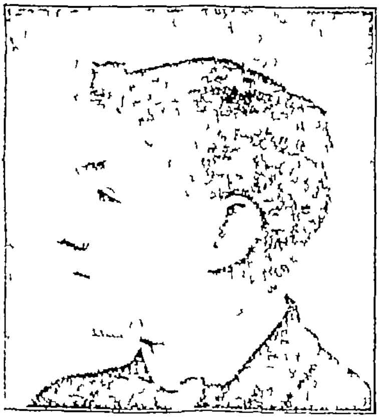
A CASE OF SADDLE-NOSE TREATED BY SUBCUTANEOUS INJECTION OF PARAFFIN

BY A. J MARTINEAU F R C.S EDIN

ASSISTANT SURGEON TO THE THROAT AND EAR HOSPITAL, BRIGHTON

A MAN aged 20 years, gave the following history At the age of 14 years he had an injury to the nose which resulted in an abscess of the septum This was treated but in the process of healing it was noticed that the bridge of the nose became depressed and the final result is shown in Fig 1. This photograph was taken at the request of a surgeon who proposed to correct the deformity by operation. Nothing was however done at this time and the nose remained in the same condition until the patient was sent to me recently by Dr R Marsh. When I saw him there was a typical saddle-nose deformity the profile view of which is shown in Fig 1. In the front view the deformity was not quite symmetrical there being a depression over the situation of the extremity of the right nasal bone. The case appeared to be a favourable one for treatment by the paraffin method, as the skin was thin and easily pinched up between the finger and thumb and there was no scar tissue.

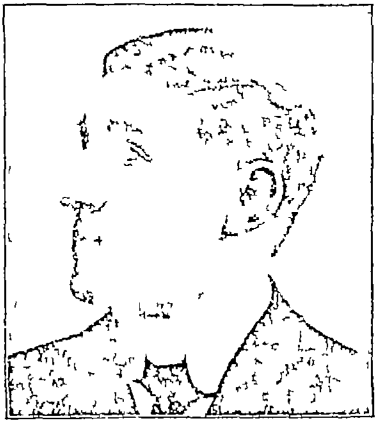
FIG 1.



Before operation.

The patient was chloroformed by Dr Marsh as he appeared to be of a nervous temperament and it was not certain how much pain would be caused by the injection of the hot fluid. The sterilised paraffin used was prepared by Martindale and had a melting point of 110° F About half a drachm was injected by means of an ordinary antitoxin syringe the above-mentioned depression being selected as the point for the insertion of the needle. The nose was then moulded into shape. For four or five days there were considerable œdema and redness of the nose but there was no pain. These subsided under cold applications leaving the nose in the condition shown in Fig 2. In the front view the nose is now symmetrical but of course it is still as broad as before.

FIG 2.



After operation

Remarks —The anæsthetic was probably unnecessary, but a case has been reported in which severe pain was caused by the procedure when performed under local anæsthesia. With regard to the melting point of the paraffin used, at first a paraffin of low melting point—e.g about 104° F —was used (Gersuny) It has been shown that this does not always give permanent results and it is found that paraffins of higher melting point—e.g from 120° to 130° F —are more satisfactory (Eckstein). In this case I chose a paraffin melting at 110° F as this seemed to me to be free from most of the defects of the low melting paraffin and easier to manipulate with simple apparatus than the high melting paraffin. It is advisable to have a special short thick needle to the syringe In conclusion, I would point out that patients are apt to be disappointed in the result at first as the front view is not much affected and they cannot at once realise the change in profile.

Hove.

THE DIAGNOSIS AND TREATMENT OF MALIGNANT STRICTURE OF THE ŒSOPHAGUS[1]

BY CHARTERS J SYMONDS, M S. LOND , F R.C.S ENG ,

SURGEON TO GUY'S HOSPITAL.

To put the subject of this debate briefly it may be said that the diagnosis of malignant stricture of the œsophagus resolves itself into the passage of a bougie, to ascertain the presence of an obstruction, and the treatment in deciding the best way of introducing food. However one sees so many cases treated for dyspepsia that it is necessary to consider a few of the early symptoms. In speaking to an audience of experts I will limit myself to what appear to me to be essential points and endeavour not to weary with unnecessary details

---

[1] A paper read before the Laryngological Society of London on June 6th 1902, in opening the discussion on the above subject

A gradually increasing dysphagia is the common history in most cases In by no means a small number the onset is sudden—e g , at a particular meal a man choked over a mouthful of meat and from that moment had difficulty Another, after shouting himself hoarse in welcoming the men from the *Powerful* in the City, had choking the same evening and developed cricoid obstruction In one instance a loathing for food so great as to require feeding by a tube was the leading sign for some weeks. In another the man complained of pain as the food passed the centre of the gullet I have seen one instance where there was no dysphagia , the man was anæmic and was thought to have cancer of the stomach, and when his evacuations were black this view was strengthened At the necropsy we found the greater portion of the œsophagus occupied by an ulcerating carcinoma, which had enlarged and not constricted the lumen at any point.

Before a bougie is passed a good many patients are treated for dyspepsia and much valuable time may be lost. One sees such patients losing flesh not so much on account of inability to swallow as because the diet has been restricted on the view that the disease was gastric It must be remembered that so called dyspepsia—i.e , loss of appetite, "tightness at the chest," waterbrash, some pain, and distension with irregular bowels—may be the result of œsophageal obstruction. The restricted diet usually prescribed tends to increase the symptoms A diagnosis can generally be made by asking the patient to swallow liquid This, when marked, is characteristic , he makes one ordinary effort followed by one or two smaller ones and these are accompanied by certain peculiar movements of the neck Then he brings up a little gas, often hits his chest and says it has gone Kussmaul's sign—viz., listening to the back to hear the fluid arrested at the stricture and then trickling through—is always interesting and when the observer does not pass a bougie is sometimes valuable I am sure from what I see that an unnecessary fear exists as to the dangers attending the use of a bougie in the minds of many Provided that a fair size be employed and no force used, and especially that no pressure be made when the patient strains to extrude the instrument, *there is no danger* The bougie should be advanced in a deep inspiration or on an act of deglutition and held still on any expulsive effort and again advanced on inspiration. That there are dangers with fine bougies and in advanced disease one cannot deny In passing the cricoid one must wait for the inspiration which follows the first glottic closure or make the patient regurgitate by passing the left forefinger far back on the tongue. To press at this moment may in close cricoid stricture send the bougie into the trachea. Once more it may be added that in impermeable cricoid obstruction, where the patient is particularly tolerant there is special risk of entering the trachea. It is remarkable to note how a patient will bear the pressure of a large bougie in the windpipe for some time without coughing In any doubt we must pass the bougie not more than 12 inches and examine its position with a laryngoscope. These special points refer rather to treatment but it seemed right to refer to them here.

With these general remarks I will next ask you to consider diagnosis of the disease as it affects the three situations—viz , the upper third and cricoid orifice, the lower end and gastric orifice, and the central region

The upper third —Stricture at the cricoid or beginning just below the ring is, in my experience, always malignant. It begins at from eight and a half inches to nine inches from the teeth and usually involves two or three inches. The chief peculiarity is the tendency to cicatrise and contract , so marked is this feature that a specimen may be indistinguishable to the naked eye from a chronic syphilitic or other ulcer If the margin of such a specimen, however, be examined microscopically squamous epithelial growth will, I believe, always be found. The contraction is irregular, so that a bougie in passing may have *to turn several corners* In the diagnosis of disease at the cricoid I have found four conditions give rise to confusion

1 The one most closely resembling organic disease is dysphagia occurring in elderly people In the first instance that came under my notice the patient was a woman, aged 70 years There was dysphagia for solids and fluids caused trouble , a bulb passed with difficulty, there was a streak of blood and altogether I thought gravely of the case and gave a serious prognosis The symptoms soon disappeared and the patient after some years is still well. A similar instance came before me again in a woman over 70 years of age and another in a man over 80 years of age In the persistence in the indefinite obstruction to a bougie, and in the age of the patient, there is sometimes a close resemblance to malignant disease There is also an absence of the nervous symptoms seen in younger people. The condition suggests some organic change, giving rise to temporary interference with deglutition I have thought that possibly an excessive cricoid ossification or some bony outgrowth interfering with movement might explain these cases

2. The nervous form, especially when occurring in men, and in medical men of all others, can only be settled by time Suddenly such a patient has difficulty at a meal over a mouthful of food and later cannot swallow a pill or a crust of bread He has to be more careful in eating than before It is well known that such is often the history of the early stages of malignant stricture The passage of a bougie is not easy, a little blood may result to further confuse the issue, or one may fail to pass the bougie beyond the cricoid without undue force Where such symptoms occur in a man of the age of 49 or 50 years the diagnosis is not easy In both affections the freedom of swallowing varies, in both soft solids are better dealt with I would say, however, that in malignant disease the patient almost always permits the passage of a bougie and that there is found irregularity of the surface indicating disease of some standing Practically in the majority there is no great difficulty, but in a few cases—especially if they happen to be medical friends—it may give rise to no small anxiety

3. The third condition is that of a pharyngeal pouch When well marked the symptoms of this complaint are so defined as to clear up quickly any difficulty The subject has been so well dealt with before this society that I need only refer to Mr H. T Butlin's communications

4 Malignant disease of the lower end of the pharynx, involving the arytenoids, cannot be excluded from a discussion upon œsophageal stricture, and as the same treatment is required I must refer to it here. The main distinctions are the pain accompanying dysphagia , the voice early has the peculiar sound produced by the presence of œdematous arytenoids , again the growth usually can be seen in the early *stages It appears first as a pale cushion* below the arytenoids and gradually advances, giving rise to early œdema of one or other arytenoid. These patients often continue to swallow fairly well and can, so far as I have seen, always be relieved by a soft tube. The direct extension to the larynx is the special feature of disease in this situation Those who have seen many of these cases will have observed the greater frequency in women and in many at an age nearer 30 than 40 years I may add that in one instance—that of a woman also—the early mass seen below the arytenoid disappeared under iodide of potassium. I have not myself encountered syphilitic disease lower than the pharynx. I have one patient with slight obstruction just above or at the cricoid who had originally—some 30 years ago—syphilitic ulceration involving the larynx.

The middle third —A sarcoma and a myoma may occur and may give rise to obstruction In one of my cases a sarcoma was found as a localised tumour, but clinically it was indistinguishable from the ordinary carcinoma. With *such rare exceptions as these all obstructions* of any moment in this section of the œsophagus are due to carcinoma It is very noticeable that aneurysm and mediastinal growths rarely give rise to serious dysphagia. Once only have I passed a bougie in a case of aneurysm and the sensation communicated to the hand was, I thought, diagnostic of the disease The patient was sent on to me with a diagnosis that mediastinal pressure was absent. The bougie passed over a convexity and smoothly descended without any difficulty Œsophageal pouches occurring in the middle and lower sections are sometimes very difficult to detect. In one patient, aged 72 years symptoms of obstruction had existed for several years , a bougie was arrested 14 inches from the teeth , *on one occasion it slipped past* and there seemed abundance of room Under chloroform the largest bougie was several times guided past the orifice. At this time he regurgitated a good third of his food For another two years he went on much the same and died somewhat suddenly from another malady There was no doubt a pouch in this case. The long duration was a strong point against malignant stricture the second that he could always take solids. In another instance a man was sent to me for pyloric vomiting , without going at length into his case I may say that the symptoms pointed to obstruction low in the gullet and the large quantity of food retained to the existence of a pouch. He was fed by a tube and the vomiting ceased. I thought it better that he should learn to feed himself in this way than undergo a gastrostomy After a year of such treatment he is in good health and able to do his work.

The lower end.—The lower end—i.e. a point from 15½ to 17 inches from the teeth—is, in my experience, the only locality where we find a simple obstruction. One is justified in saying that as the obstruction is in this situation the cause may be simple and that, the mechanical difficulty being overcome the future carries more hope than does obstruction in any other situation. I have notes of five such cases, two with pathological evidence, while three are clinical. In the first two the symptoms were those of obstruction only and they died unrelieved. One of the three living patients has had symptoms for some years and is relieved from time to time by the passage of a coudé bougie another has swallowed well since a gastrostomy was performed over a year ago never having required to use the artificial opening, while the third has had symptoms for 20 years and has required a bougie from time to time. I will again refer to the use of the coudé bougie in obstruction at the lower end let me here in referring to diagnosis insist upon its great value When a small straight bougie will not pass a large coudé may slip through easily The two specimens referred to showed a simple fibrous thickening allied no doubt to that seen in the pylorus. Slighter degrees of obstruction occur in this situation which may be called spasmodic I have seen only one marked case that of a woman aged 30 years, who when I saw her had had obstruction for 24 hours. A bougie encountered resistance, which yielded as would a tight sphincter The obstruction was definite, not a purely nervous form.

This brings me to the whole question of spasmodic stricture so-called. Personally I must express a disbelief in such a complaint, apart from the hysterical cases. Of these latter the worst two that occurred were in a boy aged seven years and in a man aged 35 years both hospital patients, and both of whom were greatly emaciated. The boy was cured by the temptation of a penny currant bun the man took a pair of the largest bougies All the cases brought to me for spasm except the hysterical, have a basis of malignant growth. I have mentioned before that in a growth in any situation there may be in the early stages much difficulty from added spasm and varying mechanical alterations in the growth itself permitting the taking of solids on one day and of fluids only with difficulty on another

When the stomach is infiltrated by malignant disease and so reduced as to hold but a couple of ounces—the so-called leather bottle stomach—the resemblance to obstruction at the cardiac end of the gullet is very close In one instance the patient could retain about one and a third ounces any larger quantity being rejected. But this amount, taken frequently was retained and the diagnosis was thus established. This was confirmed by operation. In another with obstruction at the cardiac orifice I found on performing gastrostomy only a small portion of the stomach free and available for establishing a fistula. I have no doubt that we had entered the stomach through the œsophagus and that the inability to retain fluid was due to the reduced capacity After the operation we were never able to introduce more than two ounces at a time.

Of œsophagoscopy I have no personal experience. Its value was recently demonstrated to me by Professor Mikulicz of Breslau who showed me a case of actinomycosis recognised by this method A piece of growth was removed by *forceps* and examined.

I may summarise the diagnosis in the following way:— 1 Among early symptoms we may have so-called dyspepsia, nausea, and repulsion for food pain alone when the central district is affected 2. The passage of a bougie is the only way to clear up the case and its employment need not be feared. 3. Extra-œsophageal disease rarely gives rise to serious dysphagia. 4 Spasmodic obstruction apart from the hysterical form, has always, when decided, an organic cause and this would be better called intermittent dysphagia. 5. With regard to the three special districts it may be said (*a*) that all organic obstruction in the upper third is malignant and has a special tendency to cicatrise (*b*) that in the central half of the gullet a sarcoma or a myoma, both rare diseases, may cause fatal obstruction and here also a pouch may give rise to difficulty in diagnosis but can generally be excluded and (*c*) that in the lower end alone does simple stenosis occur and here there may be difficulty in distinguishing from cancer of the stomach causing great reduction of the cavity (leather bottle stomach) 6 Finally in estimating the extent of the disease the special value of the steel bulb is noted and also the use of the coudé bougie in obstruction at the lower end.

TREATMENT

Speaking generally it may be said that we can relieve by mechanical means only and that two methods are available, one to overcome obstruction by inserting a tube of some kind and the second to open the stomach below the obstruction—i.e. to perform gastrostomy I would put the general *question of treatment in the following way as applying to* all cases 1. While the patient can swallow fluids and semi solids and while a bougie can be passed and plenty of nourishment taken he may be left alone so long as (*a*) he can swallow well or (*b*) a small bougie, No 12 catheter gauge can be passed. 2. If the dysphagia increases, even though a bougie can be passed then a tube must be inserted or gastrostomy must be performed. These conditions are seen in the soft fungating forms. 3. If a bougie cannot be passed or goes with difficulty then the same course must be followed as we know that complete closure may occur at any time. 4 If both conditions arise—i.e. the patient cannot swallow and a bougie cannot be passed—then immediate mechanical treatment is required. Probably most have summarised their treatment in some such fashion.

I have not advocated the passage of bougies with a view of dilating the stricture. It is injurious in that it irritates and leads to increase of obstruction It may split a hard stricture and set up rigor and fever from absorption. In my own practice I have abandoned this method in all malignant cases The object of the small bougie, to which I have referred is simply to secure the route, so that at any time a tube can be passed for feeding purposes or the time fixed for gastrostomy More than this has *in my experience* proved injurious As applying to all cases, I would here again refer to the advantage of attempting the passage of a tube after a night's rest and a dose of opium.

Turning next to each region in the upper third we have to note the great tendency to rapid closure and to the certainty of complete obstruction sooner or later Two methods are available here—the long feeding tube and gastrostomy Though I have successfully employed a short tube it does not, as a rule, rest comfortably unless the highest part of the stricture be at least one and a half inches below the cricoid. Of the long tubes the best is that made from rubber drainage-tube introduced by the whalebone director When this cannot be passed the retention of a silk web tube for a few days will so enlarge the passage as to enable the other to be inserted, or an ordinary urethral catheter will answer and sometimes the coudé variety will pass. If the patient be fairly tolerant the method is a useful one. The tube will last a long time—for so long as nine months. If it comes out it can always be replaced if the attempt be made at once. Should the tube, when rejected be soft and have lost its elasticity then a fresh piece must be used It should never be removed for cleaning as reinsertion may be difficult. I have conducted many such cases to the end with this tube the main objection is that saliva cannot, as a rule be swallowed, though some patients will sip fluid by the side of the tube. Another objection is that it does require some dexterity perhaps, to insert in difficult cases and much patience, but not more of either than does the passing of a catheter in stricture of the urethra. The form that I have for many years used *is somewhat* roughly made, the end of a piece of ordinary No. 10 drainage tube being sewn up with silk and a big eye cut above. Note that the end of the introducer is passed into the eye and a small plug of wool is inserted into the closed end to prevent the introducer slipping through The proof that the thinnest walled rubber tube would keep a malignant stricture dilated was first pointed out by Mr J Berry We must contrast this method with gastrostomy and I would *say that where the patient* is low and unable to bear abdominal section it is our only plan As an alternative I find that it has sustained life in comfort equal to the most successful gastrostomy and greater by far than when the stomach contents escape and cause excoriation. When the patient is intolerable and objects then we can only offer gastrostomy The longest time I have known one of these rubber tubes to remain unchanged was for 13 months. The obstruction was at the *cricoid* and great difficulty was encountered in passing the first long feeding tube The rubber form was easily introduced after a few days residence of the silk web tube From time to time small pieces of the rubber tube had to be removed, as it split near the silver cannula The patient died with the original tube in position Others have worn it for varying periods In two cases patients have also worn tracheotomy tubes One now under treatment has had a tube in for 11 months and a tracheal tube for four and a half months The same method answers admirably in disease of the larynx. In this form the obstruction to a bougie is never very great and I have had patients fed by a member of the family three or four times a day Its application is limited. After many trials I have no doubt that the best tube is the gum elastic silk-web, with a closed end and two large eyes, and the best sizes are Nos 10, 12, and 14 Smaller ones are of little use for permanent wear and dilatation up to 12 is best conducted by the long tube. The vulcanite pattern introduced by Renvers I have found of no value, it is too hard and too short The most suitable cases for this method are those where the stricture is short and has a tendency to contract, then a four inch tube answers admirably The position and length of the stricture are ascertained by a steel bulb In the central portion—i.e, for obstruction occurring from a point from 10 to 14½ inches from the teeth—we can use a short tube in addition to the long one. When introducing this method in 1884[2] I said that I hoped it would give relief in a certain number of cases, and it has fulfilled this forecast and no more The experience published in two former papers[3] represents very well the value and use of the short tube, and later experience has confirmed it. Of recent cases I may cite the following

A man, aged 55 years, had dysphagia early in 1898 On Feb 24th, 1899, a short tube was inserted The stricture, a short and contracting form, was situated 14 inches from the teeth On April 21st the tube was removed at the patient's request and there was great difficulty in inserting another On May 2nd a tube was inserted. On July 28th a new tube was introduced by Mr F J Steward On March 3rd, 1900, the tube was still in and acting well—i e., over seven months Some time later the patient showed signs of extension to the lung and died on June 3rd, 1900 Thus one tube was in for 10 months The duration of the disease before tubage was 12 months and under tubage it was 16 months, of which certainly 13 months were passed in comfort, and the man was able to attend to his business In another case the short tube acted perfectly up to the time of death, the treatment covering a period of more than a year

Disease involving the lower end and cardiac orifice I have found difficult to treat by a tube I admit that occasionally one has been successful with a short tube or a long one, but as a rule it is rejected on account of the contraction of the diaphragm. Early gastrostomy seems to me to be the best advice. I advise that this be done while the patient's general condition is good One very strong point in favour of this course is that, as I have said earlier in this paper, simple stenosis may occur in this situation Given, therefore, a successful gastrostomy life may be indefinitely prolonged. Moreover, it may be possible, especially with the coudé bougie, to dilate the obstruction after the gullet has had a good rest We may at least anticipate some return of swallowing Of course, as in other situations, operation would not be undertaken so long as a bougie could be passed freely and the patient could swallow Early gastrostomy applies especially to malignant disease in the situation I must mention one remarkable case—referred to before—that of a woman with great dysphagia and emaciation and obstruction at the lower end in whom a bougie could be passed As she lived in the country and as dysphagia was increasing I performed gastrostomy From that moment the power to swallow returned and though the second stage of the operation was completed it has not been necessary to use the stomach opening The woman remains so well now, more than a year from the operation, that I think the case must have been one of simple obstruction Dilatation could not have been effected by suturing the stomach to the abdominal wall and the only other suggestion one can offer is that a tortuosity has been straightened

In view of the occasional occurrence of simple stenosis at the cardiac orifice it seems to me our duty to press operation upon our patients when the dysphagia is marked

The use of chloroform to facilitate the introduction of a tube is a question for discussion Personally I have always had an objection to it, but I must admit that in cricoid strictures it has been of great service and deserves a wider employment. So easy is it, however, to pass a small bougie or tube into the trachea that I make it a rule after passing a tube for 12 inches to examine with a laryngoscope to see that it is really in the œsophagus In one case, when this precaution was omitted, after waiting some time and there being no spasm or cough milk was poured down and passed into the lung with disastrous consequences In another the tube passed through a tracheal fistula.

Reviewing the whole question of treatment, and contrasting tubage and gastrostomy, one may say as regards the latter that it at once disposes of all difficulty as regards swallowing, that in obstructions at the cardiac end it should be performed early, and that in all patients intolerant of the tube and bougie time should not be wasted In advanced cases, where leaking can be prevented and immediate feeding undertaken, the operation may be successful, and there is reason to expect that such a method has been found. Unfortunately, many cases among the poor are obtained in too advanced stage for operation to be considered and there are others who decline operation It is necessary, therefore, to perfect as far as possible the alternative method of tubage. With regard to cricoid strictures and disease in the lower part of the pharynx I am quite satisfied with the rubber tube and believe it to be superior to gastrostomy We want a tube so constructed that it will not be easily regurgitated and I believe this will be produced. Once a tube has been retained it is never wise to dispense with it even for a day I have several times yielded to the patients' wishes in order that they may enjoy the luxury of a solid meal and been unable to reinsert another tube. The insertion of the new tube should immediately follow the withdrawal of the old one, be it a short or a long tube The short tube has, as I said, a limited use, being of little service in disease of the two orifices But in the central section I still find it valuable It is open to the objection that it is liable to get blocked and that, again, some skill is required to insert it With cases where there is no cough I have known it remain unchanged for 10 months and in another for three months There is no necessity to remove these tubes for cleansing purposes The silk, protected as is now done by fine rubber tubing, will last for months and the security of the silk is the only anxiety When cough arises from extension of growth and hæmorrhage occurs the tube will get blocked and then a long feeding tube must be used, either a silk-web or a rubber tube

It is unnecessary on this occasion to go into details, so I will put the question of tubage as follows The short tube is useful in strictures occurring from a point 10 inches to a point 14 inches from the teeth It is of no use when there is cough on swallowing indicating perforation It is of little value when the growth occupies a long stretch of the gullet. It is seldom of use in strictures involving the cardiac orifice and cannot, as a rule, be borne in disease involving the cricoid level. In suitable cases it has, however, given good results up to the time when perforation occurs, and then as a rule a long feeding tube answers for the few weeks that remain A word must be said as to the dangers of intubation I have had accidents, fortunately, in only one case was life much shortened In one case a tube was passed under chloroform through a perforation into the trachea. This showed the danger of chloroform. In another a tube in a tight cricoid stricture passed into the trachea. The man did not cough and gave no sign that such an accident had occurred until signs of pneumonia developed In another a soft and ragged œsophagus was perforated, the man being in the last stage of the disease. These accidents occurred some years ago when I was endeavouring to improve the method of treatment Since I have systematically used the laryngoscope to ascertain the position of the tube in cricoid strictures several similar accidents have been avoided It is essential to use this check when operating under chloroform

Summary of treatment—1. In cricoid obstruction the long rubber tube gives excellent results When not well borne gastrostomy, if selected, should be performed early 2. In disease of the central portion the short tube is serviceable in a fair number of cases and when it acts well is superior to any other method It must be replaced by the long feeding tube when pulmonary symptoms arise 3. In disease of the cardiac orifice tubage is so uncertain that gastrostomy should be performed when dysphagia becomes serious.

Portland-place, W

ON PANCREATIC CALCULUS,

WITH NOTES OF A CASE.

BY B. G. A. MOYNIHAN M.S. LOND F.R.C.S. ENG
ASSISTANT SURGEON LEEDS GENERAL INFIRMARY; CONSULTING SURGEON TO THE SKIPTON HOSPITAL AND TO THE MIRFIELD MEMORIAL HOSPITAL.

THE occurrence of stone in the pancreas was first recorded by Graaf in 1667 Morgagni in 1765 and, in England, Cawley in 1788 refer to instances observed by themselves. In 1883 Johnston collected the notes of 35 recorded cases. The fullest account was given in 1896 by Giudiceandrea and was based upon 48 recorded cases and two observed by the author

The stones are generally white, greyish white or yellowish white in colour and rounded ovoid or elongated like a date stone They are found in all parts of the duct of the pancreas, though much more frequently in the head in the tail of the gland they are rarely seen. The calculi may be branched like coral, the trunk of the stone lying in the main duct and its offshoots in the secondary ducts. At times the canal of Wirsung is found packed with a coarse mortar or with sand or fine rounded pellets. The largest stone, measuring two and a half inches by half an inch, was seen by Schupmann Calculi may be single or multiple one of the most striking examples of the latter is in the museum of the Royal College of Surgeons of England (specimen 2834 Curnow s case) As many as 300 stones have been found in one case. The stones are chiefly composed of phosphorus and carbon salts. One case of oxalate of limestone is reported by Shattock. Johnston gives two analyses —

I.

Phosphorus salts	72·30
Carbon salts	18·90
Organic matter	8·80

II

Carbon salts	91·65
Magnesium carbonate	4 15
Organic matter	3·00

It is clear from this analysis that the pancreatic secretion during or before the formation of a stone is altered in quality for carbon salts are not normally present. Schmidt, quoted in Schäfer s text-book, gives the following as the composition of the ash obtained from the pancreatic juice flowing from temporary and permanent fistulæ —

—	From temporary secretion.	From permanent secretion
Soda (Na_2O)	0·58	3 31
Sodium chloride...	7 35	2·50
Potassium chloride	0·02	0·93
Earthy phosphates with traces of iron ...	0·53	0·08

The antecedent condition necessary for the deposit of stone is probably retention of the secretion. This may be produced by inflammation of the canal of Wirsung extending upwards from the duodenum, or by a chronic interstitial pancreatitis however arising Many attempts have been made by partial obstruction of the duct by ligature, by the injection of paraffin and in similar ways, to give rise to an artificial lithiasis So far as I am aware the only attempt that has succeeded was made by Thiroloix. He injected sterilised soot into the duct of Wirsung At the necropsy the pancreas was found to be atrophied and in the tail a cystic swelling containing clear watery fluid surrounded by chronic inflammatory tissue had developed. In the cyst, and in the duct also small concretions had formed.

Nimier attributes to micro-organisms a causative influence in the production of calculi. Galippe, on examining a stone, found numerous organisms distributed throughout, and Giudiceandrea discovered an organism very similar to if not identical with the bacterium coli commune.

Associated with calculi are found at times certain more or less profound alterations in the pancreas. Of such are acute and chronic interstitial inflammation, atrophy dilatation of the duct cyst, abscess fatty degeneration, and carcinoma. *Examples of cyst, dilatations of the canal of Wirsung are* recorded by Gould and Michailow Acute inflammation dependent upon calculi and subacute inflammation leading to abscess have been observed by Roddick, Körte, and Caparelli, and carcinoma by Cawley Portal, Schupmann and others.

Symptoms —So few carefully observed cases of pancreatic lithiasis have been recorded that it is impossible to give any accurate portrayal of the symptoms In the majority of examples pain, or at the least a sense of great discomfort, has been felt in the upper part of the abdomen, generally at or near the middle line and but rarely as in Minnich s case under the left costal margin. The pain frequently comes in *sharp collicky attacks, similar to, but less severe than, those* due to gall stones. A sense of soreness or stiffness is noticed for a day or two after the attack. When the pain is at its height vomiting hiccough, rigors, cold sweats, or collapse may be noticed. After the attack some fragments of stone may be found in the motions (Minnich Leichtenstern) Diabetes has been often observed. Hansemann in 72 cases of diabetes associated with pancreatic disturbances found that in 12 stone was present. Oser in 70 cases of lithiasis observed that diabetes was recorded 24 times The probability is that the onset of diabetes is due to the chronic inflammatory changes instituted in the gland by the calculus, but it must be remembered that such inflammatory alterations produce in the gland *and its duct* precisely *those changes which are* most likely to cause the deposit of calculous material. Fatty stools have been occasionally observed and in one case Lichtheim saw an abundance of fat-crystals in the fæces Rarely jaundice may be caused as related by Giudiceandrea and Pearce Gould by the pressure of the stone upon the common duct. Lancereaux states that in each attack of pancreatic colic a temporary diabetes is produced by an inhibition of the secretion analogous to the inhibition observed when one ureter is obstructed by a calculus. The cardinal symptoms of pancreatic calculus, then, are pain collicky in character similar to but of lesser intensity than, gall stone colic, and generally most intense in the epigastrium pain or *tenderness and occasionally a feeling of resistance over the* pancreas the passage of fragments of stone marked bodily wasting fat diarrhœa and in the later stages diabetes. It is rarely that all these are seen in association.

Diagnosis —Claessen in 1842 first suggested the possibility of a correct diagnosis of pancreatic calculus being made. Friedreich though he considered the occurrence of pancreatic colic not unlikely wrote The diagnosis of pancreatic calculus is impossible Material for a diagnosis was afforded by the cases of Lichtheim Minnich Körte and others In Minnich s case the pain began as a heavy pressure in the epigastrium and along the left costal margin as it increased in intensity it passed round the left side and backwards to the spine. The patient who had previously suffered from hepatic colic remarked that the character of the two pains was identical. Körte has related a very interesting and remarkable case The patient suffered from biliary colic for which the abdomen was opened a large gall stone was removed from the gall bladder which was drained by a tube While bile was still being discharged the patient suffered from what he took to be a recurrence of his attacks of biliary colic. The patient died and a tumour in the head of the pancreas which had been diagnosed as malignant at the time of the operation was found to be an abscess with large concretions within it Kümmell records an almost exactly similar case in which cholecystotomy had been performed pain recurred and at the necropsy a large soft calculus was found in the canal of Wirsung That pancreatic colic is associated with the passage of stones down the duct seems clearly to be proved by the case observed at different times by Minnich and Holzmann, for it was only after each attack that fragments of stone were found in the motions

The presence of sugar in the urine may be observed at intervals. Holzmann found it intermittently in his case. While the same patient was under Minnich s observation at an earlier date, no sugar was found though regularly sought. It is probable that it is only when advanced interstitial inflammation of the interacinar type is present and the islands of Langerhans are therefore affected that glycosuria is present. Caparelli records the case of a woman who developed, after many attacks of acute epigastric colic an abscess above the umbilicus. The abscess burst and discharged some pus and gritty material. Through the fistula which persisted for six years many small stones, over 100 in all, were expelled. After the spontaneous closure of the fistula diabetes developed and the patient died. Lancereaux's statement that in each attack of colic there is a temporary glycosuria is not borne out by the history of the case now recorded. Very careful and continuous examinations of the urine were made but sugar was never once discovered.

It is probable that the presence of fatty stools may be dependent upon the condition of the gland with regard to its ducts. If two ducts, those of Wirsung and Santorini are both present, as in the normal condition, the pancreatic secretion will not be wholly prevented from entering the duodenum by a calculus blocking the canal of Wirsung. If a single duct is present a stone impacted therein will cause a temporary complete arrest of the outpouring of pancreatic juice.

Treatment.—There is but little to say with regard to treatment. According to the results of the experimental work of Kühne and Lea the subcutaneous injection of pilocarpine incites the flow of the pancreatic juice. A case is reported from Eichhorst's clinic of "undoubted pancreatic lithiasis" in which the subcutaneous injections of pilocarpine were tried. "The attacks of colic disappeared completely and the patient was better than for many months before."

So far as I can ascertain there has been only one case of pancreatic calculus treated by operation. The case is related by Mr Pearce Gould. The patient was a man, aged 46 years, whose only previous illness was an attack of influenza four years before. In September, 1895 he noticed some failure in health and in November he suffered for a few days from severe pain which he referred to the umbilicus, chiefly felt on walking up hill. He became jaundiced and this persisted until February, 1896, when he came under observation. The liver was then enlarged nearly down to the umbilicus, the gall bladder could be felt distended as a cylindrical swelling in the right lumbar region and there was no ascites. The motions were clay coloured. On Feb 14th the abdomen was explored. Through the vertical incision to the right of the rectus muscle half a pint of fluid was withdrawn from the gall bladder by aspiration. A lump was felt at the back of the small omentum which proved to be a coral like stone in the dilated duct of Wirsung, and other smaller calculi were found and removed. The operation did not relieve the obstruction to the flow of bile and on March 3rd he had an attack of agonising pain in the right hypochondrium. Mr Pearce Gould reopened the abdomen and with some difficulty was able to feel a stone in the head of the pancreas close to the duodenum, which he removed by incising the pancreas from the front and he was then able to pass a probe through the duct into the duodenum. Soon after the operation the patient vomited bile the stools became coloured, and bile ceased to flow from the incision in the gall bladder. Notwithstanding this, vomiting persisted and he died from exhaustion on the twelfth day after the second operation. At the post mortem examination a little pus was found underneath the gall bladder and also behind the ascending colon. The pancreatic duct was found to be dilated and ulcerated. There was a hydatid cyst at the liver. The calculus was composed of phosphate and carbonate of lime.

In the discussion which followed the reading of Mr Pearce Gould's paper at the Clinical Society of London Mr T H Kellock mentioned the case of a man, aged 56 years, who was seized with acute abdominal pain followed at once by jaundice. Two weeks later he had a second attack. When admitted to hospital under the care of Dr W M Ord he was extremely jaundiced and the liver reached from the third rib to below the costal margin. On the tenth day he had a rigor followed by severe pain in the right hypochondrium and three days later he passed a small concretion, and then the jaundice became less marked but he became exhausted and gradually sank. At the necropsy the liver was found to be enlarged and the gall bladder to be dilated. Embedded in the head of the pancreas in a dilated portion of the duct was another calculus of the size of a cherry stone.

The following case has recently been under my care and as the condition of pancreatic calculus was diagnosed and successfully treated, a full account of the history may be given. I saw the patient with Dr H. M Robertson of Roundhay.

NOTES BY DR. ROBERTSON

The patient was a married woman, aged 57 years. She had had no children. She was first seen on Sept. 12th, 1901, in an acute hysterical attack. The attack subsiding careful research disclosed a multitude of symptoms chiefly of a neurasthenic type, prominent among these were the gradual and steady loss of health the loss of weight, and the development of bronzing or pigmentation very similar to that in Addison's disease which was mainly confined to the external surfaces of the forearms, the back and sides of the neck, and slightly round the nipples. A varying but slight amount of this pigmentation dates back 10 years. The patient also complained that for a long time her motions were never properly formed, either she had loose frothy stools with the occasional passing of white membranous pieces like skin, or constipation with the stools in the form of hard pellets, the colour was natural in both cases. Pruritus, both anal and vaginal, was a distressing symptom and the urine, though usually "thick" and small in quantity, was occasionally clear and excessive in amount. By physical examination nothing abnormal could at the time be detected. The patient was a well nourished woman with a fair amount of fatty tissue, despite the fact that she was seven pounds under her average weight of nine stones and four pounds and that the loss of seven pounds had occurred since the beginning of the year. The heart and lungs were normal. There was no enlargement of the liver or of the spleen. The general average of urine passed was small in quantity, under 30 ounces in 24 hours, it was of relatively high specific gravity and concentration, acid reaction, free from albumin or sugar but loaded with mixed urates and some crystals of calcium oxalate. Clinical examination of the blood and the blood count gave red cells 96 per cent., or 4 750,000, hæmoglobin 94 per cent., no leucocytosis, the percentage varying within the normal limits, the leucocyte count being 7000. The blood cells were free from degenerative changes.

With these data a provisional diagnosis was given that all the digestive, urinary, and nervous symptoms could be accounted for by the apparent lithæmia *plus* the unstable nervous equilibrium, and treatment was directed by dietetic and medicinal means towards improving the disturbed chemical and cellular metabolism that appeared to account for her condition. At the same time her husband was advised that one had an uncomfortable suspicion that some serious abdominal disease, probably in connexion with the pancreas, might be present. For six weeks treatment on the above broad lines was carried out with indefinite results. The pruritus was relieved, the condition of the stools and the regular action of the bowels were materially improved, but the old flatulence, indigestion, and slight attacks of colic were more frequent and the amount and condition of urine remained *in statu quo*. She continued to lose weight and strength and the pigmentation increased in area and depth of colour.

On Nov 4th she had a severe attack of colic, with excessive pain, sickness, collapse, &c., requiring one third of a grain of morphia hypodermically to obtain relief. The colic was so acute that it might have been either hepatic or renal, but as she had foolishly partaken freely of goose the evening before accuracy of diagnosis was not easy. Dr T Churton of Leeds, who saw her with me in consultation on that day, preferred to blame the goose, and after a careful historical survey, physical examination, and mutual discussion, he was of opinion that neurasthenia with hysteria were the more apparent causes of her condition, with the cautious reservation that while no growth or unusual condition could be detected by manual examination of her abdomen, yet there was good reason for being suspicious and careful in one's prognosis. Special measures to meet the nervous exhaustion and general debility were adopted. Rest, feeding, and massage alternated with the faradic current and the intramuscular injections of glycero phosphate of sodium (Jacquemaire's preparation). This treatment was continued for a month also with indefinite result. In some things there was improvement but there was still a steady loss of weight, an average of three or four pounds a month, her weight at this time being seven stones and 12 pounds and persistence if not increase, of pigmentation. Blood counts and examinations were made fortnightly with special reference to the leucocyte count and qualitative changes in the cells as indicative of malignant disease, always, however with negative results, and throughout the whole illness the blood count did not vary outside a 10 per cent. limit.

The urine was tested and microscopically examined each week. During the last three weeks of December there was improvement, the appetite and the digestion became better abdominal uneasiness became less the sleep was better and less disturbed the strength was slowly coming back and the pigmentation was slightly clearing. But profuse night perspirations ensued which were best controlled by a five-grain tabloid of suprarenal extract, and under its influence the total quantity of urine increased to almost normal. The patient was able to go downstairs and to get out side occasionally and continued improving till the first week of January 1902 when she unaccountably began to fall back. A slight attack of colic occurred on Jan. 9th and 24 hours later there was a distinct trace of bile in the urine and a yellow tinge began to appear in the conjunctivæ.

The stools which had been watched daily for months and frequently examined for meat fibre, &c. still kept well coloured and the jaundice, which was never extreme varied from day to day and at times disappeared so far as colouring the urine was concerned. Despite the negative results of blood and manual examination I could not but fear from the patient's condition the strong possibility of some malignant development in the region of the head of the pancreas, and wishing the case to be considered from its surgical aspect Mr B G A Moynihan kindly saw the patient on Feb. 2nd, 1902.

Chloroform was administered as an aid to more efficient examination. After discussing the possible causes Mr Moynihan gave a diagnosis in favour of chronic pancreatitis probably non malignant and possibly due to a pancreatic calculus either in the pancreatic duct or now in, or approaching the ampulla of Vater. He advised operation as at least a means of clearing up the condition but did not feel enthusiastic about the result. As the patient and her relatives were at the time averse to surgical interference it was decided to give by the mouth pancreatin and salol and then in four weeks to reconsider the case. On Mr Moynihan's suggestion a sample of urine was sent to Mr P J Cammidge at Wakefield for special examination relative to the presence of pancreatic disease and his report was, "Not a typical sample, but affords ample ground to justify a diagnosis of chronic pancreatitis." During the four weeks the patient lost four pounds in weight—being reduced now to nearly six stones—and in view of the steady progress to the bad operation was again urged and arrangements were accordingly made but in the end abandoned. A former medical attendant at this time saw her in consultation and he also advised surgical interference.

Early in April the patient was moved to a hydropathic establishment in the Matlock district to see if change would effect improvement. On the night of her arrival she had a bad attack of colic lasting several hours with increase of the jaundice and for the first time during her illness the stools were slaty in colour. During her stay of four weeks there she made decided improvement. She gained three and three-quarter pounds in weight the appetite returned and she began to feel stronger the jaundice in great part cleared up but the pigmentation remained. The consulting physician in charge wrote "that he was strongly inclined to fear malignant disease but that beyond some feeling of resistance in the epigastrium he could detect nothing definite, certainly nothing inconsistent with pancreatitis." Two days after her return home she had another attack of colic and at last consented to seek surgical relief and on May 22nd Mr Moynihan operated with the interesting result of removing from the duodenum a concretion or calculus of about the size of a French bean.

Several factors stand out as of special interest. 1 The long illness of itself but specially the length of time ere jaundice appeared as proving the real origin of the condition. 2 The value of routine blood examination as an aid to diagnosis in this case as negative of malignant disease a differential method in obscure conditions hardly appreciated by surgeons. (See Cabot, p 350. The leucocyte count of three cases of cancer of the pancreas averaged over 17 000.) 3. The peculiar bronzing which might have led one to consider the case as one of Addison's disease the patient having many other symptoms in common and later the pigmentation *plus* the progressive emaciation gave the patient the appearance of suffering from some obscure abdominal malignant disease. 4 The origin of the stone.

NOTES BY MR. MOYNIHAN

I saw the patient on Feb. 2nd 1902, with Dr Robertson. To the full and lucid statement which he has given of her condition up to the time I saw her I have nothing to add. The symptoms I had to discuss the relative value and significance of which I had to determine were briefly these steady loss of health, gradual wasting irregular pigmentation of the skin in patches of the colour of *café au lait* (very closely resembling the pigmentation of molluscum fibrosum) persisting attacks of epigastric pain and uneasiness of the type of hepatic colic though less severe and unattended until very late in the history by jaundice which was then always trivial though unmistakeable, and pain passing through from the front of the abdomen to the middle of the back. There was no rigor or any complaint of sensations of heat or cold. The stools were occasionally frothy and "greasy." On examination under chloroform some indefinite swelling could be felt above the umbilicus and a little to both sides of the median line though chiefly to the right.

I considered that the evidence warranted a diagnosis of chronic pancreatitis. To explain the onset of this condition I suggested that a pancreatic calculus was present that its transit down the canal of Wirsung had been attended by the attacks of epigastric colic, and that as it approached the ampulla an inflammatory condition had been started in the common duct and a slight jaundice had thereby resulted. Upon this diagnosis I felt justified in basing my suggestion for operative treatment. If chronic pancreatitis were found and no cause was discoverable the condition could be relieved by drainage of the gall bladder. If a pancreatic calculus were found it could be removed either from the pancreatic duct or from the ampulla of Vater if it had travelled so far. I was bound to admit the difficulties of the case and though I pressed the question of operation I felt that I could give no definite undertaking as to its result. When I saw the patient a second time after her visit to Matlock I felt convinced of the approximate accuracy of my former diagnosis and operation was at once accepted. I should like to bear tribute to the support I derived from Mr Cammidge. His examination of the urine made me feel secure in the diagnosis that I had given of chronic pancreatitis. In other cases before this one and since, I have derived considerable help from Mr Cammidge's test. One feature of the case which may perhaps be accidental is the invariable slowness of the pulse. The rate was almost always less than 60 and never higher than 64 its character was good.

Dr Churton tells me that on referring to his notes he finds that the stools were described as being at times "oily" but that he had no opportunity of verifying this observation. The husband of the patient described them to me as "greasy" but the motions that I saw showed nothing unusual.

Operation.—Operation was performed on May 22nd 1902. The abdomen was opened two inches to the right of the median line by an incision about seven inches in length and the fibres of the rectus were split. On opening the abdomen the gall bladder at once presented it was tense well filled, and free from any adhesion the cystic duct, hepatic ducts and common duct were all thoroughly examined the liver being rotated for that purpose. The ducts were all free from adhesion and nothing abnormal was felt. The head of the pancreas was very much enlarged and hard the body less so but still larger and denser than the normal. The chronic pancreatitis affected the whole gland but chiefly the head and in least degree the tail. The duodenum and the head of the pancreas were carefully examined and a small lump was then felt as it seemed between the two. The swelling did not feel like a stone and I expressed a suspicion that it might prove to be a growth deep in the ampulla of Vater. I therefore opened the duodenum and exposed the papilla Vateri this was quite normal in appearance. The lump, however was felt to be only a short distance beneath the mucous membrane. The papilla was therefore laid open and the cut edges were seized with a small French vulsellum and held apart. At the bottom of the ampulla a small object could be seen and the knife touching it could be felt to be impinging upon soft stone. A small scoop was therefore passed into the ampulla, pressure was made upon the head of the pancreas close to the duodenum and the stone was lifted out. So far as I could judge—and the ampulla was well opened—the stone lay in the termination of the pancreatic duct with its end projecting into the ampulla.

It was certainly not wholly in the ampulla, for it was not at once exposed on slitting up the papilla, equally certain it was not in the end of the common duct. The duodenum was stitched up with continuous sutures The gall bladder was aspirated and drained, and the wound was closed in the usual way The tube was removed on the seventh day and the wound then slowly healed The condition of the liver was normal. There were no adhesions around it or any trace of pigmentation

The pigmentation of the skin is one of the most interesting, and certainly the most obscure, feature of the case Interstitial pancreatitis and pigmentation of the skin are found associated in the condition described by Hanot as "diabète bronzé," but in addition a deep pigmentation of the liver with hypertrophic cirrhosis and pigmentation of the pancreas and other viscera are seen In this disease Hanot and Schachmann consider that the primary etiological factor is the diabetes, that a certain alteration in the blood, due to the diabetes, results in a disturbed nutrition of the hepatic cells in which pigment as a result becomes deposited. The carrying of the pigment to the other parts of the body to the skin and the viscera, is supposed to be in the nature of embolism Many other theories, carefully enumerated and epitomised by Opie, have been broached, but our acquaintance with the subject is at present vague and distant. The recorded cases of hæmochromatosis do not show an instance of the disease occurring in the female Within a month of the operation upon this patient the bronzed patches had shown evidence of fading especially the stained areas upon the wrists and thigh

Description of the stone removed —The stone in shape very closely resembles a French bean It is exactly half an inch in length and about three sixteenths of an inch in diameter It is bile stained on the surface The stone was cut in two for me by Mr Cammidge and the pieces were subsequently glued together after the kernel had been removed. Mr Cammidge reported that the surface layers of the stone "for about one-eighth inch are of a homogeneous consistency and light brown in colour They leave but little ash on ignition and seem to consist chiefly of cholesterin and bile pigment with some calcium salts The central portion is quite different and consists chiefly of hard granules of irregular shape On ignition they leave a large quantity of ash which seems to be chiefly calcium "

I sent a small portion of the centre of the stone to Dr J A. Milroy of Edinburgh who reported as follows "The stone contains nearly 50 per cent. of calcium carbonate. A small portion of the solution in which the magnesium was estimated was unfortunately used for qualitative testing so that I cannot state the exact quantity of magnesium present. These were the only inorganic substances found I was somewhat surprised to find phosphates absent. The organic substances consisted almost entirely of proteid Traces of organic substance soluble in alcohol and ether were present In the residue from the alcoholic and ethereal solutions cholesterin and fat were the only bodies identified Purin bases and uric acid were absent. The quantity of the original powder was rather too small to allow of an accurate estimation of the constituents "

HYPOPLASIA OF THE AORTA AS A CAUSE OF ANEURYSM

BY W LEE DICKINSON, M D CANTAB, F R C P LOND,
ASSISTANT PHYSICIAN TO ST GEORGE'S HOSPITAL.

SOME years ago it fell to my lot as curator of the museum at St George's Hospital to perform two post-mortem examinations in rapid succession on cases of ruptured abdominal aneurysm in both of which the most careful inspection failed to find any ordinary explanation of the aneurysm, such as syphilis, atheroma, or strain, but the aorta and large arteries were in a state of hypoplasia—that is *to* say, constructed upon a small and delicate scale, narrow in calibre and thin in the walls, though in all other respects practically healthy These two cases put me on the look out for arterial hypoplasia in general and as a cause of aneurysm in particular, but among upwards of 2500 post-mortem examinations that have been performed at St. George's Hospital since that time, only some three or four cases of hypoplasia have been noticed by myself or succeeding pathologists One happened to be that of a patient of my own who died from the external rupture of a thoracic aneurysm, another—also a case of thoracic aneurysm—was under the care of Dr Cyril Ogle, who kindly allows me to publish it. The first three cases have been fully described in the Transactions of the Pathological Society, vols xlv and xlix and need only be briefly recapitulated

CASE 1 —The patient was a well built man, aged 29 years, who gave no history of great exertion or strain The aneurysm, of the size of an orange, occupied the lowest two and a half inches of the aorta and the whole of the right common iliac artery, it proved fatal by rupturing into the peritoneal cavity The rest of the aorta was almost entirely free from atheroma but unusually thin and narrow, as were also all the large arteries.

CASE 2 —A woman, aged 30 years, died from the retroperitoneal rupture of an aneurysm which consisted of a fusiform dilatation of the lowest two inches of the aorta and the greater part of the left common iliac artery Immediately below the origin of the renal arteries the aorta presented a saccular aneurysm of the size of a walnut. A third, of smaller size, was found upon the left renal artery and a fourth upon the superior mesenteric The aorta was almost papery in its thinness. In the recent state it was fully elastic and faultlessly smooth but so narrow that the thoracic portion would hardly admit the little finger

In both of the above cases the large arteries were examined microscopically with the result that no fatty or other degeneration was found

CASE 3 —The patient was a coachman, aged 39 years, who had lived temperately and quietly There was no history or suspicion of syphilis The aneurysm proper was larger than a cocoanut and of true saccular form, springing from the first part of the aorta. It had caused absorption of the overlying bones and cartilages and had given rise to a secondary sac immediately beneath the integuments The fatal hæmorrhage occurred externally from the secondary sac The aorta was remarkably free from atheroma, of which, indeed there was no trace except a little roughening near the mouth of the aneurysm The vessel was somewhat small in calibre and conspicuously thin walled It was estimated that at the end of the arch the wall was not more than three fifths of the ordinary thickness The various coats were present in normal proportion and no degeneration could be detected under the microscope

CASE 4 —This case, which I owe to Dr Cyril Ogle, is of essentially the same kind as Case 3 and need only be briefly related The patient was an omnibus conductor, aged 31 years, who had been a soldier, he died in September, 1901 from the rupture of a large saccular aneurysm of the first part of the aorta into the right auricle The post-mortem examination was performed by Dr R. Salusbury Trevor, who remarked an unusual thinness of the aorta and used the expression "aortic hypoplasia" in the pathological record Dr Trevor was under no suggestion from the previous cases and his record fairly stands as the independent observation of a skilled pathologist Certain cutaneous scars were found which raised a suspicion of syphilis, but of alcoholism or undue strain there was no evidence, clinical or pathological, and the aorta was perfectly free from atheroma. The case in short was one of aortic aneurysm in which the initial lesion was possibly syphilitic, but hypoplasia was the dominating influence.

It goes without saying that congenital delicacy of the arteries when it exists, must predispose to the formation of aneurysm and favour its development, though the influence of this factor has hitherto been almost entirely overlooked Virchow, indeed, remarks upon the liability of the hypoplasic aorta to fatty degeneration of its middle coat and so to spontaneous rupture and dissecting aneurysm, but he appears not to have met with fusiform or saccular aneurysms of a chronic type in this connexion, nor is there any consideration of the subject in the formal treatises upon aneurysm of the aorta. However, the four cases given above, occurring within ten years in the experience of a single hospital, suggest that the association of aortic hypoplasia and aneurysm though rare to be sure, may yet be worth looking for in the future, especially perhaps in those cases of aneurysm which are least susceptible of explanation by ordinary causes such as aneurysms in women and young persons

As for aneurysms in women I have consulted the considerable number of reports of cases which are to be found in the works of Hope, Stokes, Walshe, Balfour and others, and in the Transactions of the Royal Medical and Chirurgical Society and of other societies, but without meeting with any mention of hypoplasia. One thing however is very striking about aneurysms in women they go from bad to worse more rapidly than in men and are much more prone to end in rupture. External rupture in particular is nearly as common in women as in men, notwithstanding the relative great rarity of aneurysm. Stokes relates three cases of external rupture two of which were in women Crisp tabulates six four in men and two in women. The records of St George's Hospital contain three in men and again two in women. We thus have 14 several cases of external rupture, six of which were in women.

Now women are notoriously more liable to hypoplasia than men and the suggestion presents itself that some degree of hypoplasia, not necessarily to be seen unless looked for may be the reason for the more untoward course of their aneurysms And so it may be with children and young persons when they suffer from aneurysm though here also the published reports are almost absolutely silent as regards hypoplasia. Still there is on record at least one case which may be quoted as showing an association of hypoplasia with aneurysm. This case is included by Mr R. W Parker in his Table of Cases of Spontaneous Extracranial Aneurysm in Persons under 20 years of age.[1] The patient was a boy aged 16 years, who died from the rupture of an aortic aneurysm into the pericardium. "The walls of the aorta were as thin as paper soft, and easily torn, but free from every kind of morbid deposit."

In another way the association of aneurysm and hypoplasia is of sinister omen—I mean as regards the prospect of cure by the deposition of fibrin. Arterial hypoplasia has long been credited with a leading place in the rather scanty morbid anatomy of hæmophilia, a disease which modern clinical pathology has proved to depend essentially upon deficient coagulability of the blood. It must be admitted that hypoplasia does not always or even generally imply hæmophilia, but at least it constitutes an ominous link between aneurysm and the possibility of a most undesirable condition of the blood.

In conclusion, I have only to say that this short paper will have served its purpose if it succeeds in drawing attention to an occasional morbid alliance the practical importance of which four cases are all too few to establish

A PECULIAR CASE OF SCARLATINA HÆMORRHAGICA.

BY VIVIAN CHASTEL DE BOINVILLE, M B.
CH B EDIN

THE following case, on account of the peculiar nature of its course, may be of interest to the readers of THE LANCET and Dr N E. Roberts, visiting physician to the City Hospitals Liverpool has sanctioned its publication. The patient was a boy aged four and a half years, who resided in Liverpool and was admitted to the Grafton street City Hospital on June 21st, 1902. According to the mother's statement he fell ill on June 16th. The admission thus took place on the sixth day after the onset of the disease, which was characterised by the usual feeling of malaise, headache, and sore throat with a cough and pain in the chest rapidly followed by a diffuse scarlet rash. On admission this rash was still visible but was fading and the fauces and throat generally were congested and foul. During the 24 hours following admission the temperature ranged from 101° to 102 4° F, falling gradually in the course of the next six days to 99 6° on the 27th. On the evening of this day the twelfth from the onset of the disease it rapidly rose to 103°, when grain doses of sulphate of quinine were administered every four hours. The temperature then again fell reaching normal on July 1st.

Thus far the case had assumed a not unusual course. The patient during this period of observation was pale and rather weak the pulse was somewhat feeble, but there was no reason to expect anything but a favourable recovery The cervical glands were not swollen. There was neither thus far nor subsequently any albumin or blood to be detected in the urine. On July 2nd however (and this is the special point in the case) just as desquamation was setting in bleeding from the anterior nares commenced Hæmorrhagic spots a dozen or so and measuring about three millimetres in diameter appeared on the anterior aspect of the scalp Similar spots presented themselves in the neighbourhood of the knee-joints. The evening temperature rose to 99 6° and the patient became generally feeble and in fact showed a tendency to collapse Perchloride of iron applied as a styptic to the nose only partially checked the hæmorrhage during its actual application. On the following day an eczematous rash appeared on the buttocks and the spots thus formed bled on the slightest friction. Tincture of hammamelis was no more successful than the former styptic in allaying the obstinate epistaxis. Iron was administered internally and brandy was cautiously exhibited. Posturing and other methods were of no avail in checking the bleeding It must be remarked that the total quantity of blood lost was very small The cause of anxiety was the symptom *per se* suggesting a markedly impoverished or poisoned state of the blood not an actual loss in quantity Desquamation which had commenced on the hands and feet, became entirely arrested The patient grew progressively weaker and the temperature rose higher—never above 103 2° however which it reached on July 6th. Tepid sponging was now employed. On the 7th, at 3 A.M. the thermometer recorded 103° Tepid sponging was again resorted to, causing the temperature to fall to 98 9° At 10 30 A.M. the patient vomited, the vomit containing a little unaltered blood At 11 A.M he died in a state of collapse.

The interesting feature of the case is of course that the hæmorrhagic symptoms did not appear at the onset of the disease as in an ordinary case of scarlatina hæmorrhagica, but at a period when convalescence was to be expected. In other words a profound toxæmia set in at a time when it was to be supposed that antitoxin in the ordinary course of *events would be forming* and immunity becoming established. Can it be that nature had as it were, surpassed herself in her process of healing that the antitoxins had become excessive and that a "reactionary anti toxæmia," if one may use such a term had set in? Or can it be that, after the supposed toxins had been sufficiently eliminated to permit of a fall of temperature and partial recovery a fresh supply of toxins hitherto combined with other material or otherwise rendered inert had suddenly become let loose in the blood and set up a secondary toxæmia?

City Hospital, Grafton-street Liverpool

VERBAL OBSESSIONS

BY JAMES SHAW M.D, M CH R.U I.

MAGNAN[1] defines an obsession as being a mode of cerebral activity in which a word thought, or image rises into consciousness—involuntarily and without discomfort when physiological, but forcibly and with painful persistence when pathological Verbal obsessions are those in which isolated words—mostly obscene or blasphemous—constitute the morbid besetment. They should be distinguished from coprolalia, obscene speech from the blasphematory mania of Verga,[2] which he described *as a special variety of obsession taking the form of oaths blasphemies, or indecent utterances* and from the onomatomania of Charcot and Magnan,[3] in which a word cannot be recollected without a painful searching of the memory or a word or phrase is ever present in consciousness and *must be emitted at intervals* its utterance being repressed for a short space only at the cost of extreme and constantly increasing mental pain In my cases the besetting words were never uttered. The words differed from psychical or psycho motor hallucinations in that they were never spoken of as "voices in the head" nor as "voices" at all Verbal obsessions may constitute the leading feature of a sort of obsessional aberration, as in the second case below, or an early symptom of a form of insanity, an obsessional melancholia, which appears to me to be as much an entity as hypochondriacal melancholia is The first case exemplifies the induction of obsessional melancholia by verbal obsessions

[2] THE LANCET April 20th 1901, p. 11[illegible]

[3] Annales Médico-Psychologiques Mars-Avril, 18[illegible]

CASE 1 —The patient was an unmarried female, aged 46 years, and had ceased to menstruate for two years She had always been "nervous," her father had suffered from neurasthenia, and her brother was "nervous" 14 months prior to my first seeing her she had had, as I was informed by her medical attendant, a slight vulvar trouble resembling balanitis in the male This had been followed by what appeared to have been an attack of influenza, for which she had not sought medical advice She had become depressed during that attack or soon after it and the depression had been increased by business worries and a monotonous solitary mode of life. When I first saw her the state of her mind had changed very little for about six weeks Her face was pale with a worried, anxious expression The left pupil was slightly larger than the right, both reacted to light Her right hand grasp was 40 and her left hand grasp was 20, her pulse rate was 96 She picked her dress with her fingers incessantly and her feet were in constant motion Neither these movements nor prolonged walking induced fatigue Her voice was low, her speech was slow and hesitant, her memory was good and her consciousness was clear She had no hallucinations She said that she was guilty of a great and unpardonable sin On close inquiry it was elicited from her that the sin was that certain words came into her mind incessantly in spite of herself. These words she did not and would not, utter She said they were irrepressible (in her mind), obscene, blasphemous, unutterable, and that the distress occasioned by them caused her to refuse food, prevented her sleeping, and had driven her to make two suicidal attempts She recovered eventually, convalescence having been preceded by some blurring of consciousness and much increase of motor agitation

CASE 2 —This case was that of a married male school teacher, aged 33 years His brothers and sisters were all "nervous," and one sister, also a patient under my care, was irritable, eccentric, incoherent of speech, and possessed of queer ideas almost amounting to delusions The patient had had influenza four years before my visit and about three years before the latter he had been much worried by an inimical female fellow-teacher After this quarrel he became weaker and less sociable Nine months prior to my visit his condition was rendered worse by the death of his brother (from Bright's disease) and his undertaking the cares of the funeral During the last three months he had deteriorated considerably and had not taught for three weeks His pulse rate when I examined him was 96, his temperature was 98 4° F, his right hand grasp was 85 and his left hand grasp was 90 (he was partly left-handed), his cutaneous sensibility, tested with a feather for touch and pain was good on the forehead and hands although he complained of feelings of numbness He wandered about restlessly putting his hands to his head, shaking his hands and gesticulating in a peculiar way, sometimes as if he were writing words in the air There was tremor of the fingers His demeanour and facial expression denoted mental pain, but motiveless laughter was frequent. Consciousness and memory were good though the patient could not fix his attention He said that obscene words arose in his mind and he could not repress them This caused him great anguish as he and all his family were very religious He said also that when he looked at any thing he could not get the image of it out of his mind (visional obsession) He fancied that fixed or heavy objects, such as pieces of furniture, moved and he would put out his hand to steady them This might have been caused by fine ocular tremor There was however no visible nystagmus On one occasion he asked to have pictures removed from a wall on which there were none He exclaimed frequently, "Oh Lord 'Oh, Lord' fell often on his knees and prayed aloud to be delivered from his evil thoughts and their cause—the obscene words These words he never uttered. He could not sleep without hypnotics and they, when their somniferous effects passed off, increased his agitation An attempt was made to obtain asylum treatment for him He was detained a few weeks in a workhouse hospital and then discharged slightly less agitated but with his obsessions as well marked as ever In that condition he remained when I heard of him two years after

Taking these two cases as types of two forms in which obsessions are prominent it will be seen that the prognosis as to mental recovery is much less favourable in the aberration almost purely obsessional than in the seemingly more formidable obsessional melancholia with its blurring of consciousness, greater mental pain and diminution of self-control, difficulty of inducing fatigue, and its presentation of a distinct fixed idea or so called faith delusion of having committed an unpardonable sin.

RADCLIFFE INFIRMARY, OXFORD

A CASE OF TUBAL PREGNANCY, LAPAROTOMY, RECOVERY

(Under the care of Dr T L KENNISH and Mr R. H. ANGLIN WHITELOCKE.)

AT the present day it is acknowledged that laparotomy is the best treatment in ectopic gestation in almost all cases The mortality from the operation is surprisingly low—for instance, Professor Mayo Robson had 22 recoveries in 23 cases and Dr J W Taylor[1] had 41 recoveries in 42 cases—that is, a mortality of less than 3 per cent.

The patient was a married woman aged 28 years She had had scarlet fever, St Vitus's dance, and rheumatic fever Before marriage which took place on Dec 27th, 1897, she had been irregular in her menses, but since then and up to the first week in October, 1900, she had always been quite regular She had had no children or miscarriages In the third week of December, 1900, she was suddenly seized with severe pain in the left side of the abdomen and was repeatedly sick and fainted A medical man saw her immediately and gave her morphia hypodermically to relieve the pain Two days later, as the patient did not improve, another medical man saw her in consultation Her account is that the diagnosis was "inflammation and stoppage of the bowels" At the end of 15 days (Jan 2nd) she was conveyed to a neighbouring hospital where she remained until the end of February Soon after her admission to the hospital she came on unwell—she had not been regular since the first week in October—and passed first a large clot and then several small ones for over a week, the discharge continuing irregularly not more than two days clear, until two days before leaving the hospital at the end of February Three weeks after entering the hospital she was she said, "put under ether and operated on for hæmorrhoids" The bowels were very constipated from the beginning She had to have repeated enemata, and in the first week the urine was withdrawn with the catheter After removal to the hospital the pain and sickness continued for six weeks She was evidently very ill, her relatives being sent for in the belief that she was in imminent danger She left the hospital on Feb 25th, 1901, and was taken to her sister's home. Dr Kennish was in bed at the time with influenza and his locum tenent saw her on the day that she went home He believed that she was suffering from pelvic cellulitis Dr Kennish saw her for the first time on March 13th and after hearing a history of amenorrhœa for two months, followed by collapse and sickness, with later the passage of clots (cast ?), and menorrhagia the symptoms appeared to him to be pathognomonic of extra uterine pregnancy, with rupture of the sac, and this was confirmed by a subsequent examination

---

[1] Extra uterine Pregnancy, 1899

On inspection of the abdomen no visible swelling was noticed but on palpation a distinct swelling of about the size of one's fist was felt in the left iliac region, slightly tender dull on percussion and evidently coming out of the pelvis. No movement or sound could be heard over it on auscultation nor could any movement be felt within it. On vaginal examination the swelling felt like a tense cyst in the left fornix and gave one the impression on bimanual examination of being of about the size of a cocoa nut The cervix was not patulous and felt normal to the touch it was drawn distinctly towards the left side—the side of the swelling The body of the uterus could be distinguished to the right and was not markedly enlarged. No sound was passed No doubt remained from the history and examination of the nature of the case and Dr Kennish accordingly asked Mr Whitelocke if he would kindly take her into the Radcliffe Infirmary for operation

On admission to the infirmary a bimanual examination revealed the existence of a large cystic mass fixed in the pelvis, adherent to the uterus extending considerably into the lower portion of the abdominal cavity and pressing unduly on the rectum. The swelling was dull on percussion and somewhat tender to the touch. No movement could be made out in it nor was there a distinct feeling of fluctuation. On describing the state of affairs to the patient she readily consented to undergo an operation Accordingly on the succeeding day after due preparation, and with the strictest aseptic precautions, Mr Whitelocke opened the abdomen through a linear incision made in the middle line between the umbilicus and the pubes. As soon as the peritoneum was opened there escaped much fluid blood containing many soft and friable clots almost black in colour These clots floated freely in the cavity intermingling with the omentum and small intestines In addition to the dark clots were to be seen others much larger firm and tough in consistence, resembling in colour a new marine sponge. These were removed from the right side of Douglas's pouch whither they seem to have gravitated as the result of a former hæmorrhage. They were removed without any difficulty In all about one and a half pints of blood were removed from the peritoneal cavity The mass could then be clearly seen to be of the nature of a tubal pregnancy The left Fallopian tube was enlarged and lay prone upon the swelling which protruded into and was incarcerated between the layers of the meso-metrium. It stripped up the peritoneum from the bladder in front and from the rectum and posterior wall of the uterus behind and extended upwards into the left side of the abdominal cavity The fundus of the uterus lay to the right of the structure. The attachments to the rectum and posterior surface of the uterus were very firm while there was perfect freedom as far as the small intestines and omentum were concerned

Finding it impossible to remove quickly the mass by reason of its firm attachment to the bowel upon which it pressed causing obstruction and judging that the projecting portion was for the most part made up of the placenta placed uppermost and that the fœtus was below Mr Whitelocke passed a large trocar into what appeared to be the amniotic cavity From this some clear fluid escaped. Following the trocar as a guide a small incision was made through the placenta and a finger was passed into the space. The manœuvre was instantly followed by an alarming hæmorrhage. Being unable to extract the fœtus which though disproportionately small could not be readily brought through the wound in the placenta Mr Whitelocke proceeded with as little delay as possible to pack the amniotic space with sterilised gauze. The bleeding which had been truly appalling ceased almost at once. The patient's condition by this time was so serious that it was obvious that she could not stand a more prolonged operation. Leaving a piece of a gauze plugging to act as a drain Mr Whitelocke proceeded as quickly as possible to close the peritoneum. But before doing so completely one and a half pints of warm saline solution were poured into its cavity This in a very few minutes had the desired effect of increasing the force of the pulse The wound was closed and the patient was sent back to bed.

The gauze packing was allowed to remain *in situ* for 72 hours. By this time the patient had completely recovered from shock and it was assumed that the sinuses in the placenta had been sealed off and a sinus-track established from the placenta to the skin wound At the first dressing when the plug was removed only about one drachm of blood escaped The sinus was kept from closing by the use of a gauze packing and the wound was dressed every 48 hours for some days. Primary union resulted except at the place kept open and there was never a higher temperature than 100° F There was no suppuration in the sinus only a little blood stained serum escaping for nearly four weeks when small pieces of placenta clots, and fœtal remains began to be extruded. This continued in varying quantities for a fortnight or more, but by the end of a month it was so scanty that she was allowed to leave the hospital. This she did on May 10th By July 15th the wound was quite healed and by a bimanual examination only a small thickening could be detected in Douglas's pouch The constipation had been quite overcome the patient was rapidly gaining in weight, and she expressed herself as feeling perfectly well.

The patient went to see Dr Kennish on Dec. 27th 1901 on account of a swelling at the site of the operation. This proved to be a hernia due to stretching of the cicatrix for which she was ordered an abdominal belt She was in perfect health and had experienced no trouble of any kind and had become quite regular again

Remarks by Dr KENNISH.—During the last 10 or 12 years a considerable number of cases of this condition have been published and the etiology has been considerably advanced The present position appears to be that the pregnancy is essentially tubal in origin and that the so-called abdominal form is but an evolutionary stage of the tubal. The possibility of primary ovarian pregnancy has frequently been disputed but cannot now be denied since the advent of the specimens of Dr Catherine Van Tussenbroek which have been personally examined and verified by Bland Sutton and others. The importance of diagnosing the condition at an early period before rupture has taken place is self-evident, but it must be chiefly by accident if it is discovered before rupture or internal hæmorrhage has taken place. The treatment is essentially surgical in all stages with the possible exception of a case when the child has reached a period near a viable age and there is good hope of preserving the lives of both mother and child[3] then in the absence of immediate symptoms the operation might be delayed. But in any circumstances the risk to the mother must be great in the early period before the fifth month from rupture and hæmorrhage and after that time, if the fœtus is living from hæmorrhage at the operation or if dead from the risks of peritonitis septicæmia or suppuration following On these grounds and from the evidence that the mortality in the pre-operative days was enormous[4] while under modern aseptic conditions it is comparatively small the balance is overwhelmingly in favour of immediate laparotomy

Remarks by Mr WHITELOCKE.—Through the kindness of Dr Kennish of Winslow I was enabled to have the care of this case at the Radcliffe Infirmary and to be responsible for the operative treatment. The patient was sent by him as a case of extra uterine gestation with a clear history of amenorrhœa for nine weeks, symptoms of internal hæmorrhage with collapse on two occasions and the passage of what was probably a decidua, followed by amenorrhœa for three weeks On admission she complained of constipation so obstinate as to amount to chronic intestinal obstruction of pain in the left side of the abdomen, and of sometimes having difficulty in passing urine A history so clear and definite taken together with the local condition would seem to have rendered the diagnosis one of simplicity yet the intestinal symptoms, obstinate constipation &c. led those who saw the case first even to operate for piles

Anatomically the case was undoubtedly one of gestation in the left Fallopian tube Rupture occurred the first time at the ninth week The shock and collapse from loss of blood seem to have been severe and her life had apparently been despaired of yet she recovered and the embryo became extruded between the layers of the meso-metrium with the placenta uppermost The fœtus still surviving the mass increased in size stripping the peritoneum from the bladder uterus and rectum and becoming so adherent to the last viscus as to cause intestinal obstruction Between the fourth and fifth month the placenta was pushed up into the abdominal cavity and then there seems to have been an ulterior extensive hæmorrhage into it. The fœtus remaining in the meso-metrium filled up the left side of Douglas's pouch and pressed upon the viscera, causing constipation and difficulty in urination. The placenta was much the larger in proportion to the fœtus.

[2] Ii ill ted by Lawson Tait Brit Med. Jour., [illegible] 1884
[3] Pozzi's Gynecology vol iii p 19[illegible] Sydenham Society, 1893
[4] Bernlets and Goupil [illegible] Sydenham Society 1865

The operation presented difficulties. To begin with, the patient was in a precarious state from loss of blood and continued confinement to her bed. The clearing out of the blood clots from the abdomen took some little time and probably increased the shock. The placenta being uppermost and adherent to the bowel it was impossible to remove it entirely or to reach the fœtus without passing through its structure. This proceeding caused alarming hæmorrhage, which, however, readily ceased when the cavity was plugged. The collapse was much diminished by the use of hot saline infusions and injections at the time of operation and afterwards. By keeping the sinus open for weeks and treating it thoroughly aseptically pieces of the mass were extruded piecemeal and satisfactorily. I am of opinion that if any more time had been lost in trying to remove either the placenta or the fœtus the patient must have died on the table; that the expedient of stuffing the cavity rapidly with sterilised gauze was a happy one, since the bleeding ceased at once; and that the subsequent drainage through a well established sinus was a less dangerous yet equally effective means of checking the gestation and removing its ill effects.

Considering the extreme danger of hæmorrhage from a tubal pregnancy bursting into the peritoneum during the advanced stages of gestation, especially when the placenta is placed uppermost, either when left alone or when dealt with by the operator, the termination of this case was fortunate. The arguments for incising and draining in these desperate cases rather than attempting to remove the placenta at one sitting seem to be supported alike by the inherent difficulty of the operation on the one hand, and the almost absolute certainty that the placenta will disappear in time if left alone, provided the fœtus perishes. From the experience gained in this case I am fully convinced that the destruction of the fœtus and the subsequent drainage constitute a safer procedure than that of attempting the removal of an adherent placenta provided thorough aseptic principles are carried out. The marked symptoms of intestinal obstruction were a troublesome complication of the condition and of themselves would have sooner or later demanded the serious attention of the surgeon.

Reviews and Notices of Books.

Charles Darwin: his Life Told in an Autobiographical Chapter and in a Selected Series of his Published Letters. Collected by his Son, FRANCIS DARWIN, Fellow of Christ's College, Cambridge. London: John Murray. 1902. Pp. 348. Price 2*s.* 6*d.* net.

THIS is an admirable book which should be read by all medical men and by all those who are interested in the progress of science. The great work done by Charles Darwin is, of course, acknowledged by everyone and no one with any knowledge of the history of the advances made in science during the last century could do otherwise than assign to him a prominent place amongst the greatest men of his time. It is, however, doubtful if more than a very small minority of those who are ready to accept these statements as truisms, could give a rational account for the faith that is in them on these points.

Most people have, in fact, accepted the doctrines which have been set before them and they know of Darwin and of his work only by reputation. Before the publication of this book a busy man might readily excuse himself on the ground that he had no time to study the question for himself. For many readers biographies are usually too long. In this volume, which the author says is practically an abbreviation of the "Life and Letters" his aim has been to retain as far as possible the personal parts of those volumes. The book contains Darwin's autobiography and reminiscences of him by his son. There are chapters on his life at Cambridge and on the voyage of the *Beagle*, and these are followed by a selection of letters connected with the great work of his life.

The autobiography is intensely interesting and the reader will immediately see in it that Charles Darwin was not only an extremely genial, kind, and loveable person, but that he had also a keen sense of humour and was by no means dull. The happiest part of his time, he said, was that which he spent at Cambridge, but in later life, in his autobiographical notes, he was inclined to speak as if he had wasted his time there; but at the date at which he wrote, he was, according to his interpretation of the Ouless portrait, "a very venerable, acute, melancholy old dog," and his remarks on his earlier adventures are no stronger than an acute old gentleman might fittingly make for the benefit of his family for whom they were written.

At one time Charles Darwin's father thought that he cared for nothing but "shooting, dogs, and rat-catching," and that he would be a disgrace to himself and to all his family. He did, in fact, become an excellent shot and whilst he was at Cambridge he adopted an unusual method of improving his eye. He got a friend to wave about a lighted candle, at which he fired with a cap only on the nipple of his gun. When the aim was true the little puff of air put out the light. Darwin's tutor thought it a remarkable thing that he should spend hours in cracking a horse whip in his rooms. He was very fond of hunting and he naturally got into a sporting set. At the same time he learned something about art, was fond of music, and collected beetles. The most important turning point of Darwin's life was undoubtedly his appointment as naturalist to the *Beagle* which sailed for the Southern Seas under the command of Captain Fitzroy.

Darwin's character became manifest by the way in which he won the respect and the love of those who went on this expedition. The commander must have been a trying companion at times, especially in the early part of the day, and the first lieutenant, Wickham, who was of course responsible for the smartness of the ship, sometimes objected to the results of the manipulative parts of Darwin's scientific investigations when his specimens littered the decks. Lieutenant Wickham considered it "d——d beastly devilment," and said "If I were skipper I would soon have you and your d——d beastly mess out of the place." To the mere "scientist" such language might have been considered opprobrious, but on the *Beagle* they jogged on very well together, the captain keeping all smooth "by rowing everyone in turn." The voyage of the *Beagle* lasted for nearly five years, and off the coast of Chili Darwin came across a curious form of barnacle, an incident, as it afterwards turned out, which profoundly affected his life.

In 1846 he began a serious study of barnacles (cirripedia), which occupied him for eight years. This prolonged and laborious work gave him the training of a scientific naturalist, and after it the work which he did became easier to him. Sir J. D. Hooker recognised three stages in his career as a biologist; he was first the mere collector at Cambridge; secondly, the collector and observer whilst on the *Beagle* and for some years afterwards; and thirdly and lastly, the trained naturalist after, and only after the cirripede work.

Much of Darwin's later work had reference to problems in botany, and he undertook these investigations untrammelled by the dead weight of technicalities which have deterred so many men who have commenced the study from pursuing it. Darwin, who disclaimed any right to be regarded as a "professed botanist," made some of the greatest discoveries of the last century. His intellect had not been dulled or his interest in natural phenomena quenched by following the botanical "scientists." "He turned his attention to plants doubtless because they were convenient objects for studying organic phenomena in their least complicated forms, and this point of view," says Sir William Thiselton Dyer, "had something of the amateur about it." He had at least the advantage of having an open mind, for from not being till he took up any point familiar with the literature bearing on it, his mind was absolutely free from any prepossession."[1]

The history of the inception of the growth and of the writing of the 'Origin of Species,' of the publication of the book, of its first reception and of the spread of its teaching is clearly and concisely given in the present volume. Charles Darwin was a man of peace who hated controversy and there can be no doubt that the book would not immediately have produced the enormous effect which it did had it not been for the vigorous championship by Huxley and the most injudicious and unfortunate attack upon it by Samuel Wilberforce, Bishop of Oxford, at the meeting of the British Association in 1860 By a strange series of chances this proved to be a great day in the history of science. Huxley had not intended to go to the meeting, he despised Wilberforce, he thought the audience incapable of forming a correct judgment on the question at issue and he had not great confidence in himself as a speaker The incident is worth recalling Towards the end of his speech Wilberforce said that he would like to ask Professor Huxley is it on his grandfather's or his grandmother's side that the ape ancestry comes in? Huxley's spirits had risen when he found that the Bishop was profoundly ignorant of his subject and on hearing this insolent question he said to Sir Benjamin Brodie The Lord hath delivered him into mine hands. He saw that the game was his. In reply to the Bishop Huxley said that in his opinion a man had no reason to be ashamed of having an ape for his grandfather, If there were an ancestor whom I should feel shame in recalling it would be a man—a man of restless and versatile intellect, who, not content with success in his own sphere of activity plunges into scientific questions with which he has no real acquaintance, only to obscure them by an aimless rhetoric and distract the attention of his hearers from the real point at issue, by eloquent digressions and skilled appeals to religious prejudice. In the course of the debate, Admiral Fitzroy remarked that he had often expostulated with his old comrade of the *Beagle* for entertaining views which were contrary to the first chapter of Genesis. There is little cause for wonder that the Oxford meeting of the British Association did much to spread the teaching of Darwin and from that time no eminent English ecclesiastic has openly attacked the teachings of modern science.

Mr Francis Darwin's book shows that Darwin must have been a man of angelic temper He went so far as to allow his morning studies to be interfered with by members of the household who entered his room for a foot rule or for a piece of sticking plaster The patience he displayed under such provocations is truly wonderful. It seems curious that a man of his intellectual capacity should have had confidence in water quacks, he suffered cures" both at Waverley in Surrey and at Malvern.

The book is extremely well written it is sympathetic and candid. It deserves to be read carefully Those who have not time to give the book a prolonged study would do well to read the autobiography (Chapter 2) the reminiscences (Chapter 4) and the chapters which relate to life at Cambridge and on the *Beagle* (Chapters 5 and 6) In regard to the letters which appear towards the end of the work all of them contain matter worth reading and this part of the book may be opened at random with the certainty of finding something of human interest. Of few books can such a thing be said. The volume is well printed and has a good index and an excellent reproduction of a photograph of Darwin taken by the late Mrs. Cameron.[2] Its price half-a-crown, puts it within the reach of everyone, and it is a book worth keeping

---

La Santé de l'Ecolier By Dr G. DELVAILLE and Dr A BREUCQ Paris Fernand Nathan. Third edition. 1902. Pp. 281.

THE need in France for a work on school hygiene, such as that before us, is probably more urgent than in this country for to a large extent the natural instinct for physical recreation which is so characteristic of English school boys and in a lesser degree of English school-girls also constitutes an effective prophylaxis against the evils which inevitably occur from the close segregation of a large number of children in class rooms. In France hygienic methods have not heretofore received the attention which they have in this country, and with a declining population and a low birth rate it is a matter of national importance to protect in every possible way the health of the rising generation. The fact that French children take little delight in organised games renders the task of maintaining discipline during school hours a doubly difficult one and at the same time makes it all the more necessary to press into the service of State pedagogy every device of practical hygiene which can better the conditions of school life. This little treatise has been mainly written for the use of teachers in Government schools or for those who are concerned with disciplinary management. It contains chapters on a variety of questions affecting the personal hygiene of the student, the care and examination of the organs of special sense, and the structure of school buildings and of class-rooms, their lighting decoration, and furniture. To the chapter on physical exercises is apportioned a totally inadequate number of pages—a number however which is possibly commensurate with the estimation in which this department of education is held in France. Gymnastics military drill skipping and bicycling (the last-named is mentioned as a new form of exercise since the publication of the last edition) are practically the only inducements held out for the physical recreation of the scholar If such be the programme of amusements offered to the children of France by those who are responsible for the direction of these matters it is little to be wondered at that the enterprise of youth discovers other and less healthy outlets for its energies The subjects so far mentioned are classified collectively as branches of school hygiene and are described in Part I Part II is concerned with the early symptoms of such contagious diseases as are incidental to school life and with the means by which they may be detected and treated Part III describes first aid in cases of emergency while the fourth and final part which will be of little interest to English readers deals with the official notices which are required by the Department of Education to be posted on the notice-boards of the schools for the efficient safeguarding of the health of scholars. Although in many respects this little volume is quite inapplicable to the conditions of school life as existing in this country it nevertheless contains many instructive suggestions for the maintenance of moral discipline which is such an important feature in the successful management of children.

Elementary Ophthalmic Optics including Ophthalmoscopy and Retinoscopy By J HERBERT PARSONS, B.S B Sc. Lond F R.C.S. Eng, Curator of the Royal London Ophthalmic Hospital. London J & A. Churchill. 8vo pp. 162. 1902.

THE object of this well written work is to enable the student to comprehend the principles which guide him in the diagnosis of errors of refraction, in the application of the ophthalmoscope, and in the employment of that mode of determining the refraction of the eye termed "retinoscopy." It is divided into 11 chapters which are successively devoted to the consideration of Light, Reflection, Refraction, Lenses, the Homocentric System, the Dioptric System of the Eye, Ametropia, the Ophthalmometer, the Ophthalmoscope (which occupies two chapters), and Retinoscopy. To read this book with advantage it is necessary that the student should possess some knowledge of trigonometry and algebra in order that he may follow the author's demonstrations, but scarcely more is demanded than a lad from the upper forms of a public school has acquired. Several figures are introduced into the text and these figures the reader should construct for himself. Many questions involving a knowledge of the laws of optics for their solution present themselves in the selection of glasses in ametropia, in the determination of the position of foreign bodies in the transparent media, and in the explanation of the phenomena observed in retinoscopy, and it would be well if all who intend to practise ophthalmic medicine and surgery were to make themselves familiar with the fundamental principles of optics. The importance of this knowledge has been clearly recognised by the opticians, and it is only necessary to point out that such knowledge forms part of their examinations and that instructive and sometimes very able articles, essays, and answers to inquiries are given weekly in the well-conducted but thoroughly business journal the *Optician*—answers that, we venture to say, could be given by but few of those students who leave our ophthalmic wards.

[2] This illustration the author says, was taken in the year 1868 by the late Mrs. Cameron reproduced in heliogravure by the Cambridge Engraving Company for the present work " Appendix II., p. [illegible]

Religio Medici, Religio Scientiæ, Religio Vitæ. By a Student of Science and Medicine, 1849–99. London: Charles Good and Co. 1902. Pp. 216. Price 3*s.* 6*d.*

ALTHOUGH of a small size this book contains a great many words, the type being small. We are led to refer to the large number of words because the main impression left by the book is that of a superfluity of language. And this is in spite of the fact that the writer has obviously spent much time in reflection and no little time in observation. Unfortunately, with the gifts of industry and meditation he does not combine that of clearness either of thought or of expression; moreover, his judgment appears to us to be often incorrect. The main thesis of his work is the absolute separation of all that is living from all that is not living. As a corollary of this separation the author to his own satisfaction, but certainly not to ours, appears to deduce the fact of a divine act of creation. We fear that men of science who take pleasure in pondering upon the mysteries of religion and of its relation to their own domains of thought—and there are many such men—will find little help from this Religio Medici. Nevertheless, the work contains some suggestive passages, gives evidence of considerable labours, and has, we may hope, provided no little consolatory meditation to at least one scientific gentleman. For ourselves, we feel after reading it like him who

> "... heard great argument
> About it and about: but evermore
> Came out by the same door where in I went."

LIBRARY TABLE

Medical Lectures and Aphorisms. By SAMUEL GEE, M.D., F.R.C.P. Lond., Honorary Physician to H.R.H. the Prince of Wales and Physician to St. Bartholomew's Hospital. London: Smith, Elder, and Co. 1902. Pp. 296. Price 6*s.*—This little volume contains a miscellaneous collection of lectures and a number of "Clinical Aphorisms from Dr. Gee's wards collected by Dr. Thomas J. Horder." The book has no preface and it is not stated whether Dr. Gee [illegible] is called "personally responsible" for the correctness of the aphorisms. Some of them should, we think, be read as apocrypha and we would not apply them all exactly as they stand "to establish any doctrine." The publication of the aphorisms will be of interest to Dr. Gee's old pupils and may well serve to recall the occasions on which the author delivered them. Many of Dr. Gee's contemporaries may also be pleased to see the book. For the majority of students the aphorisms are too condensed for easy digestion, but there are among them many wise words. We give one brief quotation on a matter the importance of which is usually under-estimated, especially by the more easy going members of the medical profession. "The risk run by bad sleepers arises not so much from want of sleep as from the temptation to fly to narcotic drugs: hypnotic is nothing but an euphuism for narcotic: the mischief lies in remedies much worse than the disease." Of the lectures, those on Asthma, Bronchitis, and Tubercular Peritonitis are perhaps the best, and the one on Sects in Medicine the most interesting. The book will prove of most interest to those who have had the most clinical experience. It is extremely suggestive.

Questions and Answers embracing the Curriculum of the Dental Student. By FERDINAND J. S. GORGAS, A.M., M.D., D.D.S. London: Rebman, Limited. 1902. Pp. 531. Price 25*s.* net.—This book consists of over 500 pages of printed matter devoted entirely to questions and answers in the various subjects embraced in the dental curriculum. In America books of this character seem to find favour but they are, we think, of little value from a true educational point of view. Text-books should give the student a clear account of the ground work of the subject treated and should make him think for himself; books of the character of the one under notice tend to make the student's learning of a parrot-like type. The printing and general "get up" of the volume are good and in addition to the ordinary index there is one arranged according to subjects.

The Roll call of Westminster Abbey. By Mrs. A. MURRAY SMITH. With Illustrations and Plans. London: Smith, Elder, and Co. 1902. Pp. 418. Price 6*s.*—Mrs. Murray Smith has produced a charming and instructive book at a very appropriate time. Bound, by the courtesy of His Majesty's Office of Works, in a cover which reproduces the blue and gold of the hangings with which the Abbey is to be draped at the Coronation of King Edward VII., this work makes a graceful gift for anyone who wishes to present a friend with a fitting memorial of the Coronation year. Moreover, the book itself provides a delightfully easy road to a very considerable knowledge of English history. We can imagine no more becoming volume for a school prize in history. Mrs. Murray Smith's writing gives that expression of ease which comes only from an author who is dealing with matters which are near to his or her heart and with which he or she is on the closest intimacy. That such is the relationship between Mrs. Murray Smith and Westminster Abbey with its numberless interests her previous works have, indeed, already assured us. To every Londoner who does not know the Abbey as he should and to every "country cousin" or foreigner who seeks a knowledge of England's Valhalla we can recommend no more pleasant, no more profitable companion, than this work of Mrs. Murray Smith.

The Tale of a Field Hospital.—Messrs. Cassell and Co. have issued a cheaper edition of Sir Frederick Treves's amusing and yet pathetic little work. The price of the first edition, a review of which appeared in THE LANCET of Dec. 1st, 1900, p. 1588, was 6*s.* The price of this cheaper edition is 3*s.* 6*d.* All the illustrations which appeared in the first edition are reproduced in the present one.

JOURNALS AND MAGAZINES

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., with the coöperation of

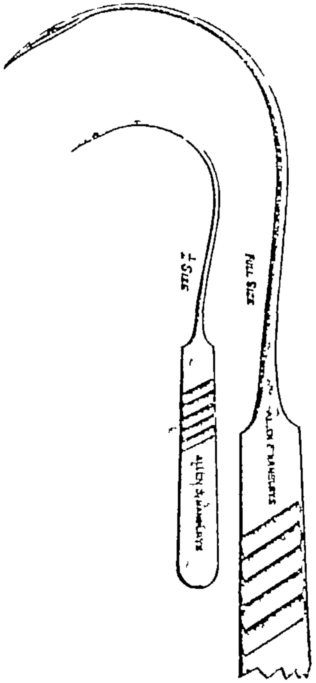
ADAM SEDGWICK, F R.S. W F R. WELDON F R.S. and SYDNEY J HICKSON, F R.S. With Lithographic Plates and Engravings on Wood. London J and A. Churchill. New Series, No 181 (Vol. xlvi. Part 1). July 1902. 8vo, pp. 143. Price 10s —The memoirs contained in this Part are 1. On a Free Swimming Hydroid, Pelago-hydra Mirabilis n. gen et sp. by Arthur Dendy D Sc. F L.S. Professor of Biology in the Canterbury College New Zealand with two plates. The specimen was picked up on the seashore at Sumner a small watering place near Christchurch on the east coast of the south island of New Zealand. It was translucent and of a pale blue colour Placed in water it presented a large balloon like structure or float " about an inch in diameter with tentacular motile processes and a proboscis which hung vertically and was about half an inch in length with a mouth at the extremity The surface of the float presented numerous branching processes or stolons which bore groups of small medusoids. The organism had a complex internal histological differentiation. The genus is closely related to the corymorphinæ of Delage and Herouard 2. Studies in the Retina Parts 3, 4 and 5 with Summary by Henry M Bernard M A. Cantab with three plates. Mr. Bernard regards the functional retina not as a structure built up of so many cells, each with some definite and permanent morphological value, but as a continuous cytoplasmic reticulum in which nuclei are suspended, and the nuclei are not stationary The rods he regards as protoplasmic vesicles thrust out against the pigment cells, which absorb the pigment granules and clarify them, the refractive contents of the rods stream away through the retina. The cases differ in the different classes of the vertebrata, but in the primates they are merely rods with swollen inner limbs. The refractive matter which fills the outer limbs of the rods is absorbed pigment, which is usually but not always clarified during the process of absorption. 3. Notes on the Relations of the Kidneys in Haliotis Tuberculata, &c. by H J Fleure, B.Sc. Aberystwyth, with a plate. 4 Notes on the Development of Paludina Vivipara, with special reference to the Urino-genital Organs and Theories of Gasteropod Torsion, by Isabella M. Drummond, with two plates. 5. Is Chemotaxis a Factor in the Fertilisation of the Eggs of Animals? by A H. Reginald Buller, B Sc., Ph.D Lecturer in Botany at the University of Birmingham.

The Veterinarian for July is deficient in original articles, being largely composed of summaries or extracts It commences with a chapter from Mr Dollar's work on Veterinary Surgery and is followed by an extract on Verminous Pleurisy in the Pig taken from the report of the chief veterinary officer to the New Zealand Government. This is succeeded by a continuation of Professor Mettam's report upon White Scour and Lung Disease in Calves, and another article on the Effects of the Liver Fluke upon Cattle, Sheep, and Swine. The Principal of the Lahore Veterinary College (Captain Perse I.C.V D) contributes an article on Suppurative Hepatitis due to Masses of Inspissated Bile, and Professor Duncan of the Ontario Veterinary College gives the result of his observations upon the weight of the kidneys in the horse. Major Ringe, I.C.V D reports upon the use of the inseminator in 28 mares, the results being entirely satisfactory as in 19 cases pregnancy was attained. Extracts from continental journals and a copy of the New Army Veterinary Warrant conclude the number In regard to the latter there is dissatisfaction expressed throughout the veterinary profession the slow rate of promotion and the decrease of pay, the invidious compound title and the want of a proper hospital staff being the main points of issue. The lack of response to an appeal for candidates to this branch of the service shows that it is very unpopular with the younger men.

New Inventions.

A NEW FORM OF PERINEUM NEEDLE

THE ordinary form of perineum needle is not well adapted to the precise needs of the situation. Most of those which I have seen are well curved but, curiously enough the curve is posterior to the handle, whilst towards the point the needle is nearly rectangular These defects greatly diminish its usefulness and I have often wondered why the instrument was made in this shape. In the needle made for me by Messrs. Allen and Hanburys, and here illustrated, the curve is anterior to the handle and is prolonged to the point With this instrument complete and accurate apposition of the margins of the laceration is readily obtained The difficulty often experienced in accurately placing the point in the right margin (when the needle is underneath the left margin and the base) practically disappears One practical detail, however needs attention. When the point is to be inserted in the left margin the handle must be well depressed to allow of the needle embracing the margin and the base this being effected the smallest amount of skill ensures the accurate inclusion of the right margin. If those accustomed to the old form will try this form of needle its advantages will I think be appreciated.



RALPH VINCENT M.D B.S Durh M.R.C P Lond.

Harley-street, W

NORTH DEVON INFIRMARY, BARNSTAPLE.—The annual report of this institution which has just been issued shows that for the year ended June 30th last the income amounted to £2135 and the expenditure to £2564 At the beginning of the year there was a favourable balance of £139 and after £250 had been taken from the reserve fund the 12 months closed with a deficiency of £40.

THE LANCET.

LONDON SATURDAY, AUGUST 9, 1902

The Coronation.

THE 9th of August, 1902, will be observed throughout the British dominions and wherever throughout the world British subjects are to be found as a day not only of national rejoicing but of deeply felt relief and thankfulness. If in THE LANCET of June 28th we had ventured to predict that the Coronation of King EDWARD VII would take place within six weeks from that date those best acquainted with the possibilities of surgery and convalescence would have held us to be over sanguine, while laymen would for the most part have frankly refused to entertain such a suggestion. Nevertheless shortly after these pages are in the hands of our readers the long expected ceremony at Westminster should be an accomplished fact, while many thousands of His Majesty's loyal subjects have been assured by ocular demonstration of their monarch's return to health and strength

Had the Coronation taken place on June 26th, the date originally fixed for it, King EDWARD and Queen ALEXANDRA would have been loyally and joyfully welcomed in their passage to and from the Abbey and during the more extended progress then planned for the following day. We can safely predict that the warmth of the greeting that will now be accorded to them will be of a different order, and that a different feeling will underlie it. The details of His Majesty's illness, of the operation performed upon him, and of his convalescence have been followed by high and low in accurate and candidly written bulletins, and these have been supplemented by such further particulars as we and our contemporaries have been enabled to give. As a result there has been impressed upon the minds of all the feeling that their King has gone through a period of great danger and acute bodily suffering, coupled with the knowledge that he has faced the one and endured the other with that courage and determination which Britons delight to honour under a monosyllabic definition as British "pluck." It was this pluck that caused him to fight against his illness until further delay would have been fraught with certain and imminent danger to life, while his reluctance to give way was caused, not by any physical dread, but by sheer sympathy with his subjects in the disappointment and inconvenience which postponement at the eleventh hour would, he knew, inevitably entail upon them. Queen ALEXANDRA ever since she was first hailed by her future subjects as her husband's bride has occupied a prominent place in their affections, but on the day of his Coronation she comes among them with her recent sorrow and anxiety fresh upon her, and the knowledge of the devotion with which she has aided in the nursing of the Royal Consort will find its expression in the enthusiasm which will acclaim her appearance.

We have referred to the episode, now fresh in the minds of all, as a period of great danger to our King. Our medical readers know well the full measure of that danger, but in the matter of the King's health we are aware that we are addressing many who are not of our profession. We wish none of those who laud His Majesty's courage and give vent to loyal expressions of congratulation up [illegible] of his illness as [illegible] disappointment sin [illegible] followed the operat [illegible] tion to health has [illegible] through which our [illegible] very real and the [illegible] ceding operation or [illegible] reminds his subje [illegible] and the artificial [illegible] modern existence in the more exalted or wealthy state of society are not the best possible prelude to an ordeal such as that through which His Majesty has come unscathed While the sinister reports concerning the King's condition were ludicrously false, we never attempted to disguise the fact that the danger was very real Those who let their memories travel back a few weeks will remember the intense anxiety which was felt by them during the week which should have been one of national rejoicing and festivity, and will perhaps recall almost with a smile the terrible rumours which were then circulated. We would impress on them that it was a time when anxiety might well be felt and expressed without those expressing it giving ground for any charge of pessimism, although it will be said, to the credit of the nation, that the public feeling was always one of dignified patience and hopefulness the expression of national anxiety never suggested the smallest approach to panic or visible excitement. It was not forgotten that to a sound constitution King EDWARD has always added a fondness for the out-of-door amusements and hardy exercise to which his subjects, whether inhabitants of cities or not, are devoted. And while the King has won popular affection as a sportsman he has no doubt done much to maintain the vigour of body with which nature has endowed him.

To the medical profession it will always be a source of congratulation and pride that the saving of the life of the King should have afforded to the world a conspicuous example of the attainments of modern professional skill. For over and above the fact of his kingship the King throughout his career has at all times used his great influence to the fullest extent, and in the most practical way open to him, for the benefit of the sick and maimed among his subjects, to procure them such aid as that which has now been afforded to himself. He has been a true friend to medicine because a true friend to the sick. On countless occasions, and notably in the institution of the Hospital Sunday Fund selected by him to commemorate the long and beneficent reign of his revered mother, Queen VICTORIA, he has gone out of his way (to use a popular expression) to show his interest in hospitals and their work. He has now reaped what he has sown, and the knowledge and skill gained in those hospitals which he has helped and encouraged have done what knowledge and skill can do towards the saving of his life. The Coronation of King EDWARD and Queen ALEXANDRA would have been in any circumstances a great national occasion unique in the experience of all but a few of their subjects. As it is it will be one unique in the experience of the world an occasion of joy and demonstrative loyalty but above all of relief and thankfulness, and of warm congratulation and welcome to our King and Queen. GOD save them both!

◆

The British Medical Association The Address in Obstetrics

FEW addresses on a special subject are likely to be read with more profit than the Address in Obstetrics by Dr WILLIAM JAPP SINCLAIR, which we publish in full at page 341. The subject of the address is Carcinoma in Women, chiefly in its Clinical Aspects," and Dr SINCLAIR claims for his subject the special interest that if the riddle of cancer is to be solved there is no form of that dread disease which is more likely than carcinoma of the uterus to lead to the explanation of the etiology of cancer

The frequency of carcinoma of the uterus and the pitiful character of its course from the social point of view lend it an interest and a pathos almost entirely its own. It affords also a promising field of clinical research from the extreme commonness of the disease, from the comparative similarity pervading the cases amidst individual differences, and from the facility with which operative and other measures can be employed. But most of all perhaps, should carcinoma of the uterus claim especial clinical attention from the extreme importance of early diagnosis and from the encouraging results which surgery offers when careful clinical examination places patients sufficiently early within the reach of hopeful operative interference. If it enforced no other doctrine Dr SINCLAIR'S address would repay careful reading for the emphasis with which he preaches this great lesson that physical examination must follow immediately on the practitioner's part when he is confronted by a patient whose age and symptoms render the existence of cancer of the womb in the least probable. Dr SINCLAIR is not of that school which takes a pessimistic view of the doings of surgery in this particular region. True he sees little encouragement in the recent radical operations by which an extensive dissection of the contents of the pelvis with removal of glands and lymphatics and re implantation of ureters damaged by the way seeks to ensure no recurrence of the disease Such an operation, if it removes all the disease unfortunately also removes all chance of a comfortable existence if not of existence at all Such irrational and unlimited proceedings do not appeal to Dr SINCLAIR. Nor have their results any encouragement to offer to the judicious observer From the *operation of* vaginal extirpation however results of constantly increasing hopefulness are now obtained and it is upon this operation, supported by the all important early diagnosis that Dr SINCLAIR bases his claim for an improved future as regards the treatment of cancer of the uterus. His figures show that at present we in Great Britain have not yet reached the position of success, as gauged by the figures that has been reached by surgeons on the continent. But early diagnosis of a large percentage of cases of cancer of the uterus will assuredly be followed by results as good as those shown by our continental *confrères*.

Dr SINCLAIR believes as a matter of fact that further scientific knowledge *of the exact nature and of the true* cause of cancerous disease awaits rather scientific clinical observation than purely experimental or microscopical work What may be termed the destructive part of his address is occupied with a critical survey of the results which have been obtained in these fields in the search for a fuller knowledge of the cause of carcinoma. Dr SINCLAIR places the value of microscopical and inoculation work in the investigation of cancer of the uterus far below the value of minute clinical investigation and this he does without belittling the services of bacteriological work in other directions. It is to clinical investigation that he strenuously directs the attention of practitioners and it is to this the practical the hopeful side of his remarks that we are particularly drawn. We would not, any more than would Dr SINCLAIR, for one moment undervalue the industry the honest endeavour and the talents that have embellished the labours of scientific explorers in the domain of clinical pathology But we may well ask with him, ' What *have investigations* and *researches* into the etiology and pathology of cancer done for clinical gynæcology?" More urgently still we would ask, What experienced gynæcologist can safely trust to the microscope and the microtome when his own finger and eye do not guide him in the diagnosis of cervical cancer? *And is it not of infinitely* greater importance that the practitioner of medicine should realise the importance of understanding the bearing of clinical facts should grasp the immense influence of early examination and should reap the knowledge that comes from an educated finger rather than that he should be aware of the possible value of obtaining a small specimen for microscopical examination? We trust that Dr SINCLAIR'S address will awake many of our readers to fresh efforts in investigating every clinical fact that bears upon the course and perhaps upon the cause, of the cases of carcinoma which they meet.

◆

The London Water Bill An Appeal to Mr Balfour

THE change in the Premiership gives the Government not only an excuse but a reason for giving a little careful consideration to the London Water Bill. Lord SALISBURY as Prime Minister and as Foreign Minister always and rightly gave his first thought to foreign affairs. No other English statesman has any knowledge approaching that which the late Prime Minister possesses of the complicated conditions which govern the relations of the great powers of the world. It was for that reason that he was able to maintain the position of this country in a time of dire distress with a calmness a dignity and a completeness which were entirely worthy of the successor of PITT It was because his mind, his constant thought, and his traditional interests were bound up with the governments of countries that he looked upon many of the domestic struggles in politics with a detachment which was practically indistinguishable from indifference. The true explanation of this attitude was that Lord SALISBURY believed that, for good or for evil, under a democratic form of government the people entrusted with the power must judge for themselves in all home affairs. On the alcohol question he pointed out that it was often useless to make new laws when those already in existence were not enforced, and he explained to the bishops that people with cellars of their own were not always ready to appreciate the position of others who relied on those of a public house.

When Lord SALISBURY received a deputation from some representatives of the Metropolitan Boroughs who desired that the London Water Bill should provide for the representation of the municipal authorities on the Water Board he pointed out that the London County Council held that it ought to be the water authority and that the Metropolitan Boroughs thought otherwise, and he told the deputation in effect that he thought each party had the right to its own opinion and that they must fight it out. It did not appear that he took much interest in the matter, the question was eminently one which should be decided by the "parties interested." Such an attitude is one which Lord SALISBURY had a right to take, but it is not one which can be rightly adopted by his successor. Mr BALFOUR will be expected by the enormous number of persons who are interested in the matter to understand the London water question. But he will not be able to understand it without devoting some time and thought to it. And it is quite time that he should begin to do so. Up to the present time his remarks on the subject have not been fortunate. In one of his election speeches he said that he would not allow the London water supply to be treated as an Imperial question. It is not an Imperial matter, but it deeply concerns the people of London, and their patience has been so unwearied that both of the great political parties appear to agree in one thing, if in one thing only—that the interests of the London people may be safely ignored. In one of his latest speeches Mr BALFOUR said that we should hear less about London water if the Opposition did not wish to prevent the people in the country from being educated. The attitude of the Opposition does not concern us in the least, we have no political bias, the Opposition cannot pass a Bill, moreover it favours the acquisition of the water supply by the London County Council and we have given our reasons for believing that this policy is opposed to the interests of the people of Water London.

We wish briefly to call the attention of Mr BALFOUR and of his Government to some points in the London Water Bill as it stands in its amended form. We have already shown at length why the Bill as originally drawn was a thoroughly bad Bill. It is in some respects worse in its amended form. It may be well for us to repeat that we entirely disapprove of purchase of the present water businesses at the present time on behalf of the London people. But, supposing for a moment that purchase were desirable, the scheme for payment for the undertakings which was devised by Mr BANBURY and adopted in the original Government Bill was a better plan than that provided for in the Bill as amended. The water companies naturally supported the amendment. In the second place we must call attention to the way in which the hands of the arbitrators are tied. The question is a financial one with which we do not feel it necessary to deal, but we may at least ask Mr BALFOUR whether it is not the fact that the proposed Water Board is to be compelled to purchase the undertakings at a price which is to be determined by the dividends paid by the companies during the last few years? If Mr BALFOUR does realise the effect of such an arrangement it is evident that some supporters of the Bill do not, for one of the Wandsworth borough councillors in a letter to the *Times* has suggested that the only thing necessary for the protection of the financial interests of the London people is that they should be properly represented at the arbitration. Lord LLANDAFF thought it would be fair that a company which had a prospect of increasing its dividends should receive compensation on that account, and that in case of prospective decrease of dividends a corresponding deduction should be made in the purchase price of the business. Is Mr BALFOUR aware that some of the companies have only been able to pay their present dividends because they have neglected to spend money in providing sufficient plant for the adequate treatment of the water which they distribute? and is it not a fact that the arbitrators, far from being "free and unfettered," are not allowed to take such matters into consideration in assessing the amount of payment to be made to the companies as dividends till the discharge of compensation?

When there has been much discussion on any subject people often say "Something must be done." Then they do the wrong thing. London Conservative Members of Parliament wish to be quit of the London water question. Mr WHITMORE, for example, was eloquent for days at the Llandaff Commission against purchase of the undertakings, now he favours their purchase. Yet the water-supply is the same. Unnecessary as it may seem, it cannot be too clearly insisted that a change of ownership in itself will neither increase the quantity of the water nor improve the plant at present in existence. The great problem which will have to be solved is whether the present sources of water are adequate in amount. Lord BALFOUR'S Commission advised that they were sufficient. It has since been proved that the evidence on which that opinion was formed was contrary to the facts. The engineer to the New River Company gave evidence which he has since acknowledged was erroneous and he is unable to account for the mistake. The New River Company and the Kent Company have persistently declined to give information as to the state of their wells. There is a general opinion amongst independent water engineers, and a universal opinion in the districts themselves, that Hertfordshire and Kent are being depleted of their water and that the supply in the future (especially in the former county) will be less than it has been in the past. Lord ROBERT CECIL could probably convince Mr BALFOUR on this point in less than five minutes. It would be manifestly unfair to force the London people to buy undertakings of the details of which they are ignorant. There is no doubt that as time goes on more water will be used in London. In the language of water engineers more water will be "wasted"; for example, the streets will be thoroughly washed. The water companies are under a statutory obligation to supply water at a reasonable price for this purpose and the present time with awakening London municipalities is not a judicious one at which to interfere with this arrangement, and it is not reasonable to form a Water Board to undertake duties which it would by the very nature of things be unable to perform.

There are, indeed, many reasons which show the inadvisability of purchase of several of the undertakings at the present time. We have lately described in detail some of the deficiencies of the present undertakings; it must suffice to recall a few of the points. The East London Waterworks Company has not sufficient sources of supply. At the present time it obtains water from other companies. For the water abstracted at Sunbury from the Thames by this company no provision is made for its storage and sedimentation. The filter beds are supplied by crude river water. The Grand Junction Waterworks Company is greatly deficient in storage and sedimentation reservoirs. The Lambeth Waterworks Company is deficient in storage and sedimentation reservoirs and in filter beds. It follows from these gross deficiencies that the company usually supplies dirtier water (or in diplomatic language "water of a deeper average tint of brown") than that supplied by any other company. The company has also failed to make provision for the continuous supply of water to its customers.

These facts are, we are quite ready to believe, new to Mr. BALFOUR. We call his serious attention to them and we ask him whether in the light of them he still thinks it fair that a new board can reasonably be required to purchase these undertakings and to become responsible to the London people for an adequate supply of water of good quality?

Annotations

"Ne quid nimis."

THE KING'S HEALTH.

THE return of His Majesty the King to London on Wednesday formed an ocular proof to thousands of his loyal subjects that his convalescence is established. He has borne the journey to London without fatigue and is in excellent health. The wound is practically healed.

THE KING'S SANATORIUM: THE PRIZE COMPETITION FOR THE ERECTION OF A SANATORIUM IN ENGLAND FOR TUBERCULOSIS.

THE Advisory Committee appointed by the King in connexion with the erection of a sanatorium for tuberculosis in England announce that 180 essays were sent in in competition for the three prizes sanctioned by His Majesty. The terms of the competition will be found fully announced in THE LANCET of Jan. 4th of this year. The Advisory Committee—Sir William Broadbent, Sir R. Douglas Powell, Sir Felix Semon, Sir Hermann Weber, and Dr. Theodore Williams—are unanimous that the following essays are the best, and with the approval of His Majesty the prizes will be awarded in the order mentioned:—

FIRST PRIZE.—Value £500.

Motto: "*Give him air, he'll straight be well*."—Dr. Arthur Latham (London), with whom is associated as architect Mr. William West (London).

SECOND PRIZE.—Value £200.

Motto: "*If preventable why not prevented?*"—Dr. F. J. Wethered (London), with whom are associated as architects Messrs. Law and Allen (London).

THIRD PRIZE.—Value £100.

Motto: "*Vis medicatrix naturae*."—Dr. E. C. Morland (Croydon), with whom is associated as architect Mr. G. Morland (Croydon).

Dr. Arthur Latham is assistant physician to St. George's Hospital and to the Brompton Hospital for Consumption; Dr. F. J. Wethered is assistant physician to the Middlesex Hospital and to the Brompton Hospital for Consumption. Dr. Morland has somewhat recently completed a distinguished career at St. Bartholomew's Hospital by taking many prizes and holding the coveted junior appointments. We congratulate these three gentlemen on their success.

The following four essays being judged by the Advisory Committee to be "of great excellence" are awarded honourable mention:—

Motto: "*Fac recte nil time*."—Dr. P. S. Hichens (Northampton), with whom is associated as architect Mr. R. W. Schultz (London).

Motto: "*Open air everywhere*."—Dr. Turban (Davos), with whom is associated as architect Herr J. Gros (Zürich).

Motto: "*Honesta quam magna*."—Dr. Jane Walker (London), with whom are associated as architects Messrs. Smith and Brewer (London).

Motto: "*Humus*."—Dr. J. P. Wills (Bexhill), with whom is associated as architect Mr. Wills (London).

DR. JAMES GREY GLOVER.

WITH unfeigned regret we have to announce that Dr. Glover has intimated to us his wish to retire from active work as a member of the editorial staff of THE LANCET. His connexion with our staff commenced in June, 1862, under the editorship of the late Dr. James Wakley and has continued uninterruptedly to the present time. During this long period of more than 40 years we have invariably found him to be a true, trustworthy, and sagacious colleague and a personal friend of sterling worth. As happily he will read these words we must refrain from the full meed of praise that is his due, but he knows, we think, how highly his services have been appreciated by us and he has been so kind as to tell us that the appreciation has not been wholly on one side. Dr. Glover's many friends will be glad to hear, as we are to relate, that his health continues good, that he is still actively engaged in professional work, and that his interest in all that concerns the reputation of the profession and the welfare of its members is unabated. In the name of our predecessors in the editorial chair and for ourselves we thank him for the work which he has done and for the time which he has expended in the service of THE LANCET. Perhaps we may go further and thank him for all that he has accomplished or tried to accomplish, on behalf of the profession which he loves so well. May he be spared for many years to come, no longer, it is true, as a [illegible] of the General Medical Council [illegible], but still as a [illegible] general [illegible] man of honour, probity, and good [illegible] the best interests of his fellow creatures generally and his brethren in medicine in particular. Our [illegible] but is tempered by the knowledge that we shall still have the benefit of his criticism in the future as in the past, for it should be known that, greatly to his credit as an independent thinker, Dr Glover has never spared us criticism (considerately conveyed) when the editorial policy has not fully met with his approval In the words of Rip Van Winkle "May he and his family live long and prosper "

AN AGE LIMIT IN ELEMENTARY EDUCATION

No one who approaches the subject with an open mind and some knowledge of the facts related to it will deny that there are weaknesses in our present system of public education which call for effective treatment. It has done good but it has by no means realised the expectations founded on it. On the other hand, it has done many things which the majority of persons probably neither expected nor desired that it should do Nevertheless, there is health in it and some hope of better administration under a more intelligent policy To arrive at the basis of such a policy should constitute the starting point of a much needed reformation in its modes of operation For this reason the opinions of careful and suggestive critics are worthy of consideration as much by school boards or their prospective representatives as by the people of this country Dr Arthur Newsholme, medical officer of health of Brighton, is a critic of this kind In a paper entitled "The Lower Limit of Age for School Attendance " he discusses the propriety of admitting children under five years of age to public elementary schools, and states the reasons which have led him to decide in favour of their exclusion The first seven years of life, he reminds us, are years of rapid growth and are clearly intended by nature to be allotted practically to the fulfilment of this purpose alone More particularly is this true of the five earliest years To exact from the brain any systematic work during this period is to use it altogether prematurely and to induce a corresponding exhaustion of its working material He argues further that liability to infectious diseases and the fatality resulting from them are both markedly more noticeable before the age of five years Tables quoted from the ninth and latest annual report of the medical officer of health of the County of London and from a paper by Dr Laing of Aberdeen in *Public Health* for July, 1902, alike bear out this contention Consequently, it is of great importance to the well being of these children that they should be as little exposed as possible to the danger of infection This danger is more unavoidably present in public elementary schools than elsewhere. Such are the chief objections urged in this paper against the school attendance of very young children Some of the advantages alleged to result from such attendance are quoted also It is said to suit the convenience of working mothers that their younger children should be for some part of a day off their hands By the same arrangement the attendance of the older children in a family is more or less assured Finally, the infants are early introduced to the regularity and the work of school life In the opinion of Dr Newsholme neither of the two former considerations ought to be allowed any weight in comparison with the physical and mental requirements of the infant scholar The last he does not regard as an advantage but the contrary He shows that even the kindergarten work scheduled by the Board of Education as being suited to children between three and five years of age, though it does, of course, appear very simple from the adult standpoint, is too complex for the very unformed brain of a young child Such work as "word building," "recitation" arranging "pictures of number" and counting on beads implies a kind of mental occupation too regular and sustained for an infant whose brain tissue is still in this early developmental stage. As a matter of fact we are assured that the school-work of infancy goes beyond this and that a large amount of instruction in reading, writing, and arithmetic is got through before the close of the fifth year The course pursued in England as compared with that in Scotland is suggestive in this connexion In England 10 9 per cent. of the total number of children in elementary schools are under five years old, in Scotland the percentage during the same period is 2 2. After the sixth year the Scottish ratio rises above the English, and according to the report of the Royal Commission on Elementary Education for 1897 the percentage of scholars who passed in specific subjects amounted in Scotland to 26, as compared with 2 3 in England. Thus it does not appear that a much earlier introduction to school life carries with it a promise of educational advantage, but rather that its effect, if any, is prejudicial Certain it is that the relative lack of an early forcing bed for the mind has not prevented the exhibition of thinking power during the most fruitful years of the school period. We have no hesitation in indorsing the view taken by Dr Newsholme in this carefully studied paper that the systematic school-training of children under five, and even under six, years of age confers no appreciable educational advantage but may easily become, and probably does become, in a number of cases a cause of premature brain exhaustion and tells against, not in favour of, the later progress of the scholar It is a hopeful sign that opinions as rational as those expressed in this paper are so firmly supported by one whose official position brings him into frequent contact with the sanitary aspects of school life In these days of superabundant zeal, when reflection is apt to appear but a secondary consideration, it may not be found a waste of time to pause awhile to ask whether a plan of elementary education a good deal simpler than that which we have now, and seemingly somewhat slower but not less thorough (which, after all, is more like nature s way), would not be found the most useful in the end

MEDICAL ASPECTS OF MOUNTAIN TUNNELLING

AT a meeting of the North of England Institute of Mining and Mechanical Engineers held in Newcastle last April, Dr Thomas Oliver of that city gave an interesting account of a visit to the works now in progress at the Simplon tunnel This tunnel will be traversed by a railway connecting Brigue in Switzerland with Domo d'Ossolo in Italy The distance between the two portals of the tunnel is 12 26 miles or 64,692 feet, it was commenced in November, 1898, and the contractors have undertaken to complete it in May, 1904 Of the long Alpine tunnels already in use, the Mont Cenis tunnel is eight miles in length and required 13 years for its construction, the St. Gothard tunnel is nine miles in length and required less than 10 years, the Brenner tunnel consists in reality of a series, no separate member of which is so long as the foregoing During the construction of the St Gothard tunnel (1872–80) 600 workmen perished, including the engineer and the contractor This enormous mortality was attributed to a combination of insanitary conditions, such as insufficient ventilation, the high temperature, which at one time often rose to 107° F , excessive moisture of the atmosphere, exposure of the miners to an Alpine climate on emerging from the tunnel and want of care on their part in not changing their wet clothes, the inferior quality of the food, and the ankylostomum duodenale, which, owing to the uncleanly habits of the men was conveyed from one person to another through the medium of the drinking-water Dr Oliver s visit to the Simplon tunnel works was undertaken mainly with the view of learning something of the hygienic and medical problems raised by the massing together of thousands of workmen in a remote valley He found that the conductors of the enterprise were strongly impressed with the importance of having healthy men for the work, sufficient house accommodation for them and their families, and good ventilation in the tunnel. The temperature in the tunnel was at first often as high as 98° but by driving in air with fans it might be brought down to 68° For every cubic foot of air that was sent into the St. Gothard tunnel 50 cubic feet are being introduced into the Simplon tunnel. At Iselle, on the Italian side, nearly 2000 men are employed, of whom 1500 work in the tunnel divided into three batches working an eight-hours shift, so that there are always 500 men in the tunnel. On leaving off work they are brought out in a train from which they pass directly into a large wooden building suitably warmed where they have a warm bath, put on warm dry clothes, and leave their wet working clothes to be dried in readiness for wearing next day The hospital at Iselle is a two-storeyed wooden building under the care of Dr Volante and contains 24 beds, the wards and operation room *were extremely clean and well kept, the antiseptic* treatment of wounds was carried out with scrupulous fidelity So far the construction of the tunnel has been remarkably free from loss of life, as from November 1898 to the end of May 1901 there were only six deaths from accidents, but there have been plenty of minor injuries. Bronchitis and rheumatism were the diseases of most frequent occurrence Intestinal catarrh was also common there had been no enteric fever or ankylostomiasis At Brigue, on the Swiss side of the mountain, the system was practically the same as at Iselle. More men were employed there than at Iselle and the hospital under the care of Dr Pommata was a little larger At the end of February 1902, the Brigue end of the tunnel had advanced four miles and a half while the Iselle end had advanced nearly three miles, or a total of 7 5 miles out of the 12 26 miles to be excavated

---

OLEANSING WORK IN THE CITY OF MANCHESTER

MANCHESTER is by no means solely a water closet city It might be supposed that there was trouble enough with the disposal of the matter carried through its sewers but in addition to this there are the contents of thousands of privies to be dealt with and the other solid refuse of a great *population These are disposed of in great part at* Carrington Moss and Chat Moss. The latter estate comprises 2579 acres, is between six and seven miles from Manchester and has a frontage of one and a quarter miles to the Ship Canal. The total cost was £138,520 It was bought in 1895 and up to March last the amount expended for the works necessary for the development of the estate, for the building and repair of farmsteads, reconstruction of roads and drains for a wharf on the canal and for a light railway for the conveyance of manure to the tenants was £60 040 The rents received from all sources on the estate for the year ending March 31st amounted to £5081. From December 1898 when the wharf on the canal was first used to March 31st, 1902, 208 349 tons of material have been received there and despatched by the light railway of which there are about 10 miles, to various parts of the estate. The Carrington estate is about 10 *miles from Manchester and is in Cheshire. It* was bought in 1886 for £39 165, and since then £43,976 have been spent on drainage, light railways and farm and other buildings The valuation in March, 1901, was £118,354 This property comprises 1101 acres and at the time of purchase 600 acres were wild moss and plantations and the rest were only partially cultivated. Since that time the wild moss and the partially reclaimed area have been brought into a thorough state of cultivation, and if some one who only knew it of old could see it for the first time under its changed condition the transformation would appear almost magical. The corporation uses nearly 60 acres as a nursery on which it grows shrubs for the Manchester parks, while nurserymen and market-gardeners occupy a considerable area. The manure and refuse sent from Manchester by canal and rail during the 14 years ending March 31st last amounted to 661,236 tons. The rents received for the last year came to £1986. Chat Moss will no doubt be gradually converted into valuable agricultural land in a similar way and though the collectors of rare insects may lament, the people of Manchester need not do so. A few grouse lingered at Carrington Moss till quite recently It is difficult to see how Manchester could have dealt with her refuse without Chat Moss and Carrington Moss, and the scale of the Cleansing Committee's operations enable the mind to obtain some idea of the difficulties of sanitation where large populations are concerned

---

EXPERIMENTS ON HEREDITY

A MEMOIR of exceptional interest has been recently published by the Royal Society dealing with the subject of heredity It is the first report to the Evolution Committee upon experiments undertaken by Mr W Bateson, F R.S. and Miss E R. Saunders Recognising the fact that variations of animals and plants may be distinct phenomena, according as they are continuous or discontinuous, they thought it desirable to ascertain in as many cases as possible which variations belonged to each of these categories. With this object in view they proceeded to test each character separately by direct experiment in cross-breeding Further they proposed to test the possibility that in breeding might have a specific effect in modifying the power of transmitting parental character to offspring This subject had already attracted the attention of a Silesian priest, named G J Mendel, who 60 years ago made a very large number of experiments upon the *Pisum sativum* varieties of which he crossed. His mode of procedure was to select pairs of varieties for crossing in such a way that the members of each pair differed from each other in respect of one definite character such as shape of seed whether rounded or irregularly angular and deeply wrinkled; colour of cotyledons whether yellow or green colour of seed skin whether *brownish or white* shape of pod, whether simply inflated or deeply constricted between the seeds colour of unripe pod, whether a shade of green or bright yellow, position of flowers whether distributed along the stem or crowded near the top in a false umbel and length of stem whether six or seven feet or about one foot. Between these various pairs of varieties crosses were then made, the female parent having the anthers removed. On the examination of the offspring Mendel found that in the case of each pair of characters one only was manifested in every cross-bred individual to the total or almost total exclusion of the opposite character The character which prevailed was termed the dominant the character which did not appear the recessive or shortly D and R. In each of the above pairs the dominant was the first. Reciprocal crosses gave identical results, so that D crossed with R or R × D gave offspring which in appearance are all practically D The next generation was obtained by allowing *the cross-bred* plants to fertilise themselves and Mendel found that this generation, instead of being uniform like their parents, broke up into the two original form but in such proportion that on the average there were three dominants to one recessive The recessives were thenceforth actually pure and if allowed to fertilise themselves gave rise to recessives only for any number of generations The dominants though apparently alike, could, if allowed to fertilise themselves, be shown to consist of pure dominant which on self fertilisation gave rise to dominants only individuals which were cross breds gave rise on self fertilisation to a mixture of dominants and recessives again in the proportion of three to one as before. The pure dominants were to the cross bred dominants as one is to two. Mendel considered that his facts pointed to the conclusion that in the cross bred each of its pollen grains and each of its egg cells was either a pure dominant or a pure recessive and that on the average there were equal numbers of each kind for each sex. If the assortment of pollen grains and egg cells was then supposed to take place at random, the most probable percentage result was 25 D 50 D R 25 R. But as cross breds resembled dominants in appearance the apparent result was 3 D 1 R at each successive self fertilisation of cross-breds. Analogous experiments have been made by Professor Correns, by Professor de Vries, by Professor Tschermak, Mr Trevor Clarke, and by the authors of the memoir, the plants experimented on being the common stock, lychnis, atropa, datura, and other plants. The essential result is the evidence that the germ cells or gametes produced by cross bred organisms may in respect of given characters be of the pure parental types, and consequently incapable of transmitting the opposite character, and that when such pure similar gametes of opposite sexes are united together in fertilisation the individuals so formed and their posterity are free from all taint of the cross, that there may be, in short, perfect, or almost perfect, discontinuity between these germs in respect of one of each pair of opposite characters. Mr Bateson and Miss Saunders, in the first part of their memoir, give the details of a large number of experiments which they have made on various plants, and these appear to support the statements of Mendel. In the second part of the memoir the authors took poultry as the subjects of their experiments, matching Indian game with brown Leghorn, white Leghorn, white Dorking, and a white Wyandotte hen. The results again appeared to support Mendel's statements. The new views naturally require a nomenclature, and this is introduced to the reader in the following terms. "By crossing two forms exhibiting antagonistic characters cross breds are produced. The generative cells of these cross breds are shown to be of two kinds, each being pure in regard to *one* of the parental characters. This purity of the germ cells and their inability to transmit both of the antagonistic characters is the central fact proved by Mendel's work. We thus reach the conception of unit characters existing in antagonistic pairs." Such characters Mr Bateson and Miss Saunders propose to call "allelomorphs" and the zygote formed by the union of a pair of opposite allelomorphic gametes they call a "heterozygote". Similarly the zygote formed by the union of gametes having similar allelomorphs may be spoken of as a "homozygote". Many facts are given, many authorities cited, and many conclusions drawn in the memoir for which we have no space, but the extracts which we have made will show the general trend of the authors' work.

SMOKY CITIES

WE were recently compelled to remark unfavourably upon the smokiness of Manchester and the injury which thereby accrued to both public health and public buildings. In doing so we were by no means unmindful of the fact that London is far from being as free from dirty smoke as it should be. The Public Health Acts and the efforts of the Coal Smoke Abatement Society have done, and are doing, something to make the atmosphere of London a little purer than it was in the middle of the last century, but still much remains to be done. This point has been brought forcibly before the notice of Londoners by a remark of General Lukas Meyer who, on being interviewed as to his impressions of England, said "Everything in England so far as I have been able to see it is pleasing except the soiling of your city buildings by black smoke." The factory chimney has been attacked with success, but there still remain offenders in the shape of electric lighting shafts, the chimneys of restaurants and hotels, the chimneys of small bakehouses, and in greater numbers than all the chimneys of private dwelling houses. It would be impossible to reform all the domestic grates at present in use, but surely the County Council, which is the building authority for London, might make it compulsory for every new house that is built within the metropolitan area to be fitted with a grate which at all events is calculated to emit as little smoke as possible. There is no perfect domestic grate, but the tests initiated by the Coal Smoke Abatement Society which were described in THE LANCET of May 10th, p 1342, show conclusively that some grates are much better as regards the emission of smoke than are others. We cannot hope that we shall ever get a South African atmosphere in London but a good deal might be done to free town dwellers from the *fumum strepitumque* which, if they annoyed Horace in Rome, would do so ten times more if he were with us in London.

THE DISTRIBUTION OF PLAGUE

THE weekly return of the Director General of the Sanitary Department in Egypt shows that for the week ending July 27th there were 8 new cases admitted, 1 of which occurred in a European. The deaths numbered 5, the recoveries 1, and 19 cases remained under treatment. With respect to sanitary measures, 15,696 rooms were disinfected and 613 were lime washed, 173 sacks of effects were disinfected, and 1432 sacks of rubbish were burnt. The number of rats killed and burned was 995.

TYPHOID SPINE

THE term "typhoid spine" was applied in 1899 by Gibney to a condition resembling Pott's disease, which occasionally follows typhoid fever.[1] 29 cases have now been recorded. Gibney thought that the condition was due to inflammation of the structures surrounding the vertebræ—perispondylitis. In the *Boston Medical and Surgical Journal* of July 17th Dr G W Moorehouse has recorded the following case. A man, aged 28 years, had a severe attack of typhoid fever with a relapse. He entered hospital at the beginning of the second week of the attack and was discharged on June 10th, 1899, after a period of 10 weeks. Widal's reaction was obtained. While in bed there were no symptoms referable to the back but when he sat up or walked about the back felt weak and ached. 10 days after his discharge the pain rapidly increased and occurred in attacks lasting for an hour or two, with intervals of three or four hours of comparative relief. Movement was liable to bring on an attack but one often occurred without assignable cause. The attacks were more frequent in the night than in the day. The pain was localised in the lower lumbar and sacral regions and in the buttock—most commonly in the right, sometimes in the left, but never in both buttocks. Periods of a few days of normal temperature alternated with similar periods of pyrexia in which the temperature sometimes rose to 103° F. On August 23rd, when the patient was readmitted to hospital, the pain had diminished and was confined to the lower lumbar region. He was somewhat emaciated. There was no spinal deformity or tenderness. The Widal reaction was negative. The temperature in the first month varied between 98° and 99.5°. Then it began to rise and on Sept 25th reached 103.6°. The febrile period lasted two weeks. On Oct 2nd the spleen which was said to be of normal size on re admission, was felt below the ribs and Widal's reaction was obtained. In the last week in October slow and steady improvement began. He was discharged on Dec. 13th having still some trouble with his back. He was soon free from pain but his back felt weak and on several occasions he feared a relapse He did not attempt to return to work in his office until May 1900, 13 months after the onset of the typhoid fever During the whole summer the back felt very sore for a day or two after any mis-step or over-exertion He is still liable to this soreness but in less degree.

---

[1] New York Medical Journal 1899 vol i p 596.

THE PREVALENCE OF SMALL-POX

THE following figures show the number of patients admitted to the various hospitals of the Metropolitan Asylums Board for the dates mentioned On Saturday August 2nd there were 6 fresh cases, on Sunday the 3rd there were no fresh cases on Monday the 4th there were 7 fresh cases, on Tuesday the 5th there were 10 fresh cases, and on Wednesday the 6th, there were 2 fresh cases.

THE CLOSING SCENE AT NETLEY

In the present number we give a short account of the proceedings at the last distribution of prizes in the Army Medical School at Netley The next session of the school will commence in London on Sept 1st and will be attended by the medical men on probation for both the Royal Army Medical Corps and the Indian Medical Service The abolition of the Army Medical School is not the only momentous change taking place at Netley for i has been determined that the office of assistant adjutant general shall not be refilled—an excellent arrangement, for the principal medical officer will now reign supreme in every portion of the great establishment and will for the first time assume the extensive responsibilities and position which should always have been his Lord Roberts who has the enviable faculty of always saying the right thing at the right time recalled in his address to the newly appointed officers the good works of their fathers in the Indian Medical Service There is perhaps no greater incentive to good work than for a man to feel that he belongs to a body with traditions. The Indian Medical Service is one of which we are all proud and we doubt not that its great traditions will be still further handed on by the most recently appointed members of that service.

A TERRIBLE EXPERIENCE

MR. MALCOLM M. MCHARDY, professor of opthalmology at King's College has recently passed through a thrilling experience, fortunately however attended with no worse result than that of a broken rib. He was yachting with a friend Mr Philip Herbert, in the Channel and on July 26th Mr McHardy and Mr Herbert, together with a paid hand left Netley for the Essex coast in a 10-ton decked yawl All went well until a gale sprang up at night when on a heavy sea striking the yawl Mr McHardy was jerked overboard. He was wearing oilskins heavy clothing and sea boots, so that his chances of escape seemed small. Although not an expert swimmer he is a stout man and therefore he did the best thing possible under the circumstances —namely turned on his back and floated. Mr Herbert on missing his friend turned the yawl round and sailed her back on her old course as nearly as he could guess Mr McHardy saw the yawl and hailed her upon which he momentarily sank. Mr Herbert then left the yawl in charge of the third hand cast off the dinghy and pulled toward Mr McHardy He was unable to get him on board, so he fastened a line under his arms and towed him back to the yawl. With great difficulty Mr McHardy was got on board, the dinghy meanwhile having sunk. His watch had stopped at 9 17 o'clock and it was 10 27 when he was finally got into the saloon, but except for his broken rib which probably was fractured by his being jammed between the yawl and the dinghy, he is we are glad to say none the worse We congratulate him and the other members of the crew upon the pluck and presence of mind which they displayed To be thrown into a stormy sea with heavy clothing on is by no means a pleasant situation, and yet perhaps the fact of Mr McHardy's clothing being so thick saved him from death when he was nipped between the yawl and the dinghy Mr Herbert is, we understand a skilled seaman but this in no way detracts from his pluck in going to the rescue in a small boat. The resolution which he displayed in his successful effort to save his friend's life is past all praise

MANCHESTER ROYAL INFIRMARY POLL.

THE voting papers for or against rebuilding the infirmary on the present site were returned on Saturday last and have now been counted. 1248 papers were issued, of which 757 were returned 199 trustees voted in favour of the motion to rebuild in Piccadilly 550 voted against it and eight papers were irregular The majority against rebuilding on the present site was therefore 351, a very decisive majority Whether the board will accept the mandate of the trustees and adopt a scheme for placing the infirmary elsewhere or—what would be very unfortunate—resign as a body remains to be seen. It is to be hoped that having been beaten they will still work loyally for the interests of the charity and help forward the building of an enlarged infirmary at Stanley Grove or on a more convenient and better site if one can be found

THE medical excursions to German watering-places and health resorts to which reference was made in THE LANCET of July 19th p. 171 are intended to give medical men an annual opportunity of visiting localities interesting from a balneological point of view Dr W H. Gilbert of Baden Baden, the general secretary now announces that applications from gentlemen desirous of joining this year's excursion will be received up to August 15th.

THE Select Committee appointed to inquire into the ventilation of the Houses of Parliament has presented an interim report in which the chemical and bacteriological tests made in the debating chamber during the session are referred to. At this stage, however the committee is not prepared to draw up any recommendations and it is proposed to continue the inquiry during the autumn

AT a meeting of the American Congress of Tuberculosis held in New York on June 3rd 4th and 5th a suggestion to hold a World's Congress of Tuberculosis in St. Louis in 1904 was approved, and steps are being taken to advertise this fact and to secure the aid of medical journals, societies physicians, and scientific men in making the movement a success.

MESSRS. M. N. ROTHSCHILD and Sons have given £1000 and the Leathersellers Company £250 towards the £100 000 required for cancer research by the Cancer Research Committee

---

FACTORY GIRLS COUNTRY HOLIDAY FUND.—An urgent appeal on behalf of this fund has been issued by the committee No class of workers need an annual holiday more than do the factory girls of our great city As the committee point out The factory girls of London need a break in their lives—not for their own sakes alone but for the health and stamina of those who come after them. To contribute to this holiday fund is thus indirectly a contribution to imperial defence" Subscriptions and donations should be sent to the honorary treasurer Mrs Bedford, St Peter's Rectory Saffron hill London E C.

THE BRITISH MEDICAL ASSOCIATION

MEETING AT MANCHESTER.

OWING to the changes involved by the adoption of the new constitution of the Association there was no formal closing general meeting The recommendations sent up from the sections were considered at the Council meeting held on Friday, August 1st.

On Thursday, July 31st, the Anglo American Continental Medical Society gave a luncheon at the Grand Hotel. The chair was taken by Dr F M Sandwith of Cairo, and among other members present were Dr G Sandison Brock, Rome, Dr A. R Coldstream, Florence, Dr W Page May, Assouan, Dr Leonard N Robinson, Paris, Dr D W Samways, Mentone, and Dr Stuart A. Tidey, Florence Among the guests were Sir W Broadbent, Professor Clifford Allbutt, Dr J F H Broadbent, Dr H P Cholmeley, Dr G B Ferguson, Dr H. W Gardner, Professor J Symington, and Dr James Taylor The chairman proposed the health of the King and the health of the guests, to which latter Sir William Broadbent replied Professor Clifford Allbutt proposed "The Society" and referred to the value of the society as a bond of union This was responded to by Dr Samways and shortly afterwards the proceedings terminated. The annual luncheon of the Anglo American Continental Medical Society is a pleasant little function and affords an opportunity to members of the profession whose spheres of work are in widely separate orbits to meet each other and interchange ideas

The annual dinner was held on July 31st at Platt Hall, Rusholme, Manchester The chair was taken by the President of the Association, Mr Walter Whitehead, and the number of members and guests present was nearly 300 After the usual loyal toasts had been proposed and duly honoured Sir Thomas Myles gave the toast of "The Navy, Army, and Auxiliary Forces," which was responded to by Surgeon General Hamilton, whose remarks in regard to the excellent work rendered by the medical service during the late war were received with great enthusiasm Dr S Woodcock in a very witty speech proposed the toast of "The Bishop, Clergy, and Ministers of all Denominations," which was suitably acknowledged by the Dean of Manchester and by the Rev Mr Brown of the Roman Catholic Church of the Holy Name Sir Frank F Adam gave "The Houses of Parliament and the Colonial Legislatures," which was replied to by Sir James Graham and the Hon W G Rockwood. The toast of "The British Medical Association" was entrusted to Professor Rotch. Dr W A. Elliston submitted the toast of "The City of Manchester and the Royal Borough of Salford" which was acknowledged by the Lord Mayor of Manchester and the Mayor of Salford. Sir James Grant proposed and Principal A. Hopkinson replied to, the toast of "The Owens College" The remaining toasts were "The President" and "The Guests" which in spite of the late hour of the evening were received and acknowledged with great enthusiasm by the numerous company During the dinner a charming programme of music was executed by the Band of the 2nd Volunteer Battalion Manchester Regiment and was much appreciated

The closing entertainments on Friday, August 1st, consisted of a reception and conversazione given in the town-hall by the Lord and Lady Mayoress and a ball at which the guests were received by the President and Mrs Whitehead.

THE SECTIONS

MEDICINE

THURSDAY, JULY 31ST

DR THOMAS BUZZARD (London), in opening a discussion on

The Differential Diagnosis of Functional and Organic Paralysis,

remarked that the expression "functional" as employed in this country was scarcely ever met with in the writings of continental authorities, where cases of this class were always called "hysterical." Without attempting to define the word he thought that for the purposes of the discussion it would be convenient to consider it as applied to cases of paralysis which simulated more or less closely those arising from structural alterations of recognised character within the nervous system without being dependent upon any changes that the most advanced means of investigation enabled us to distinguish He also thought that the term should be limited to cases of paralysis of a kind which it would be possible for at least some healthy persons to produce by voluntary simulation This was not to imply that they were so produced (he entertained no doubt about the reality of the disorder) but in order to exclude from the category such examples as paralysis confined to the district of a single nerve root or trunk of a mixed nerve. Functional paralysis could sometimes (though by no means always) be removed rapidly or suddenly as a result of persuasion or physical or moral check. He enumerated many symptoms which were conclusive as to the existence of organic disease and thought that, on the other hand, there were probably none which, unsupported, could be relied upon to establish a diagnosis of functional paralysis Functional hemiplegia was rarely preceded by anything resembling apoplectic seizure, it was most commonly of somewhat gradual onset and was principally differentiated by its failure to present that gradual passage from flaccidity to contracture which was characteristic of the organic form It was prone to be associated with an amount of anæsthesia far exceeding that usually observed in organic hemiplegia, except of that form in which there was lesion of the sensory tract in the internal capsule The points of difference between organic and functional hemianæsthesia were considered Reference was made to the characteristic hysterical gait This had been well described by Todd, to whom they owed also the observation that hysterical hemiplegia rarely, if ever, attacked the face Apparent exceptions to this experience were described. Attention was drawn to Babinski's "flexion combinée de la cuisse et du tronc" as an important test. In organic hemiplegia an effort to sit up in bed without the aid of the arms caused the heel of the affected side to be lifted, which did not happen in the functional form Although a process of slow and gradual contracture was not prone to occur in the course of functional hemiplegia a strong contracture (without previous flaccidity) might take place often suddenly and might present a very strong *primâ facie* resemblance to the result of an organic lesion. In such circumstances a point which he (Dr Buzzard) had described many years ago was useful for differential diagnosis In true hemiplegic contracture of long standing, he had pointed out, the whole arm could not be passively extended at one moment, but in the functional form the arm, the hand, and the fingers could all by an effort be brought into one plane. He did not think that inequality of the deep reflexes on the two sides could be absolutely relied upon to prove that the hemiplegia was of organic origin, though it was, without doubt, a very strong indication in that direction, and the same obtained with regard to ankle clonus, which was sometimes, though very rarely, in the functional form, indistinguishable from that characterising organic lesion Dr Buzzard said that many years' continuous experience had entirely confirmed an observation published by him some 20 years ago as to the absence or difficulty in eliciting plantar reflex in functional paralysis, and he thought the symptom was of great service as a negative sign in differentiating functional from organic paralysis The "toe phenomenon" described by Babinski in 1896 was probably of still more importance since it gave positive evidence of organic disturbance Monoplegia of functional origin was then discussed and it was shown that although in many cases the character of the affection could be conclusively demonstrated its differentiation might sometimes present insurmountable difficulties Paraplegia, he thought, rarely presented any serious difficulty, especially because of the aid to diagnosis afforded by the Babinski toe phenomenon and his own symptom of absent plantar reflex. Some remarks were made on the electrical condition sometimes observed in muscles in cases of functional paralysis which might tend to cause misapprehension and the various signs indicating functional paraplegia were described. Some remarks on the comparatively moderate and often transitory paralysis of a limb or limbs in insular sclerosis concluded the address. Attention was drawn to the extreme frequency with which this was erroneously regarded as of functional character and how much deplorable injustice was thereby inflicted on the numerous sufferers from this disease. He combated the idea held by some that these attacks of localised paralysis were at first hysterical and eventuated in organic change, and expressed the opinion that it was the attack of structural disease in the central nervous system which incidentally caused also hysterical symptoms. Not only physical shock, but the shock of structural disease, was prone to induce along with its immediately resulting symptoms others of a functional and often transitory character In conclusion, he pleaded for the medical student receiving accurate instruction and study of the Babinski toe phenomenon as a most important means of differentiating organic from functional paralysis

Sir **WILLIAM BROADBENT** (London) remarked on the facility with which early cases of disseminated sclerosis might be mistaken for functional paralysis. His experience confirmed what Dr Buzzard had said on the diagnosis of the various forms of monoplegia and paraplegia. Sir William Broadbent wished to draw special attention to the extraordinary vascular changes which might be associated with functional paralysis—e.g the actual increase in the volume of the limb and the changes in colour which might occur in limbs the seat of functional paralysis.

Dr **E F TREVELYAN** (Leeds) referred to cases illustrating some points in the diagnosis between functional and organic paralysis. He mentioned cases of aphasia in Graves s disease, temporary hemiplegias in tabes, partial paraplegias and brachial and crural monoplegias. In a case of very localised paralysis of traumatic origin affecting the thumb simulation could be excluded. To illustrate the incongruousness of symptoms in functional paralysis he referred to a case in which a functional aphonia was accompanied by a typical and almost incessant hysterical cough.

Dr **JUDSON S BURY** (Manchester) thought that a sharp line of division should be drawn between cases of malingering and another group of cases which might be functional or organic in origin. He remarked on the impossibility of finding an infallible sign for distinguishing functional from organic paralysis and he would not like to regard Babinski s sign as an infallible sign of the presence of organic disease He referred to cases under his care which made rapid recovery which were certainly not functional Cases called functional were not really functional there must be some anatomical change, some change which came on and which could go away suddenly though its nature could not yet be defined.

Dr **E. S REYNOLDS** (Manchester) drew attention to the importance of the subject under discussion He thought that there was a marked increase in malingering and compensation cases since the enactment of the Workmen s Compensation Act. He referred to cases of malingering which could be readily detected by anyone with a knowledge of anatomy In disseminated sclerosis considerable difficulty sometimes arose but it was not insuperable. Ankle clonus with very rare exceptions, only occurred in organic disease Babinski's sign checked and counteracted this when it worked." A patient s gait should always be investigated with bare feet and then it afforded most valuable aid. It would then be noticed that the big toe instead of being turned up vertically as in organic contracture, was turned downwards quite flat upon the floor

Dr **T D SAVILL** (London) remarked that the chief difficulty in the diagnosis of functional paralysis (as distinct from malingering which belonged to a totally different category) lay in its distinction from syphilitic, embolic, and peripheral lesions all of which might occur at the same period of life and in the female sex. There were three features upon which he wished to lay stress The first was the absence of signs peculiar to organic disease, such as optic neuritis or valvular disease. Optic neuritis never occurred in functional cases, but there was nevertheless a very characteristic alteration in the vision in many cases—namely a concentric retraction of the fields of vision and an inversion of the red and blue fields Professor J M. Charcot had first drawn attention to this. Secondly there were certain special characteristics attaching to the individual symptoms in functional cases. A sudden onset in a female patient dating from a fright, worry or nerve-strain" was strongly suspicious Anæsthesia was very frequent. Sometimes it was scattered, sometimes it occupied one-half of the body and strange to say like functional hemiplegia, two-thirds of the cases were on the left side. Briquet s exhaustive analysis gave 85 per cent.[1] But in the third place, of all diagnostic features the variability and incompleteness of the motor or sensory symptoms were the most valuable. The symptoms might last on and off for an indefinite time in one case which he had seen recently they had lasted for 28 years but they varied widely in degree from day to day or hour to hour There was no other clinical manifestation which could appear and disappear so suddenly and so completely Did not this suggest a transient vascular lesion in the nervous structures involved? Moreover when thoroughly investigated these cases often presented transient erythemata and other neuro-vascular phenomena, such as the swelling of a limb to which Sir William Broadbent had just referred and in his (D Savill s) view the symptoms were due to a transient internal vaso-motor lesion of that kind—a view which was supported also by other investigations upon which he was engaged.

Dr **HARRY CAMPBELL** (London) found a difficulty in drawing a sharp dividing line between functional and organic disease. Taking myasthenia gravis, Landry's paralysis the ocular paralysis and Graves's disease by way of illustration were they he asked, organic or inorganic? Again was the loss of knee-jerk observed in the early stage of diphtheria and diabetes organic? Genuine ankle clonus and Babinski s sign he regarded as absolute signs of organic disease. The pupil might be temporarily fixed in hysteria. Diplopia was an equivocal sign. He had observed a degree of hemianopsia in hysterical hemiplegia and had read of fixed pupil recurring in hysteria from spasm of the sphincter pupillæ.

Dr **F W MOTT** (London) referred to the cholin test as a possible means of distinguishing organic and functional paralysis, but he would not like to claim infallibility for it. The proportion of cholin found in a person s blood bore a direct relation to the amount of nervous tissue which had undergone degeneration. Dr Mott and Professor Halliburton had examined cases of disseminated sclerosis, myotrophic sclerosis, beri beri and a very large number of cases of general paralysis of the insane. Traces of cholin had been found in normal blood and in the blood in other diseases by some observers, therefore the test was a proportionate one It was necessary to draw five or 10 cubic centimetres of blood from the arm. This was treated with six or eight times its bulk of alcohol to get rid of the potash salts, and the cholin crystals which formed were afterwards washed with alcohol This, the chemical test for cholin was comparatively simple but the physiological test could also be employed Cholin produced a fall in the blood pressure of an animal and this fall could be prevented by the previous injection of atropin

Dr **DAVID DRUMMOND** (Newcastle) wished to insist on the value of certain signs as indicative unequivocally of organic disease, such possibly as Babinski s sign and possibly ankle clonus though the latter might be present in hysteria, a case being mentioned in illustration. It had been stated that aphasia and relaxed sphincters were never met with in functional paralysis but this did not coincide with his experience.

Dr **PURVES STEWART** (London) said that he would confine his attention especially to one point—the postures assumed by patients in cases of organic paralysis as contrasted with those of functional disease and he illustrated his remarks with lantern slides First, as to organic paralysis they were familiar with the postures which were gradually assumed by the paralysed limbs whether hemiplegic paraplegic, or monoplegic in distribution. Those postures of organic paralyses were determined by anatomical rules Thus when one group of muscles were paralysed from a nuclear or infranuclear lesion (as in disease or injury of anterior cornua, anterior nerve-roots or peripheral nerve-trunks) the unopposed antagonists slowly fixed the limb in a definite

---

[1] Traité Clinique et Thérapeutique de l'Hystérie Paris 1859

posture, which was not only easily recognised but could be predicted beforehand Several examples of such contractures were shown on the screen Again, if from a supra-nuclear lesion, the muscles of a limb or of a segment of a limb were all more or less paralysed and the "pattern" of contracture depended upon the relative strength of the different spastic and paralysed muscles The muscles which were normally more powerful were placed at an advantage, so that, for example, in hemiplegia the familiar posture of the upper limb was one of flexion with pronation, that of the lower limb being one of slight flexion at the hip and knee with extension and some inversion at the ankle and a tendency to dorsiflexion of the toes But in *functional paralysis* the conditions were different Hysteria, it was said, often simulated organic paralysis—e.g in a functional hemiplegia, paraplegia, or monoplegia. But on careful examination the posture was found to be not quite the same in organic and in functional contractures, the latter not being governed by the same definite anatomical laws Dr Stewart then exhibited a lantern slide of a case of functional hemiplegia in which, instead of the flexed pronated posture of the upper limb noted in the other case, the elbow and wrist were extended, the hand supinated, and the fingers half bent into a hook-like posture. And in the lower limb the inverson of the ankle was overdone, it was out of all proportion to the equinus condition. This contracture had developed quite suddenly, as it so often did in cases of functional contractures Lantern slides were next exhibited showing that the posture of the foot in walking differed in organic and in functional paralysis But although an organic type of contracture was always pathognomonic of organic disease the converse was not always true In disseminated sclerosis paralysis of a characteristically "functional" type would sometimes be observed In a certain proportion of cases a patient with disseminated sclerosis might have a coexisting paralysis of a "functional" type In fact, the existence of a functional type of paralysis should always lead them to consider the possibility of disseminated sclerosis in the background.

Dr John M MacCormac (Belfast) remarked that the differential diagnosis between organic and functional paralysis was often a most difficult problem and they had always to bear in mind that in organic disease symptoms of a functional nature might be present It was well known that in the earlier stages of certain degenerative diseases of the central nervous system (e g, disseminated sclerosis), symptoms apparently functional might coexist in their way In his experience paralysis of the external ocular muscles was almost absolute proof of organic intra cranial disease The only exceptions to this rule were those very rare cases of ocular palsy dependent on toxæmia, epilepsy, or migraine The loss of the pupillary reaction to light (in the absence of the influence of certain drugs), the Argyll Robertson pupil and well marked and persistent hemianopia, invariably pointed to organic disease. The eye condition in which Wernicke's sign was present invariably indicated a lesion posterior to the geniculate bodies Paralysis of the face and palate with very rare exceptions pointed to organic disease. A genuine loss of the knee jerk was almost conclusive proof of organic disease and so also was ankle clonus which had steady rythmic vibrations for a considerable time of six or seven per second. In hysterical palsy a clonus of very brief duration or with an inconstant rate of vibration was occasionally met with, and the abolition of pharyngeal and plantar reflexes coexisting with an increase of the other reflexes was proof that the condition was functional

Dr Julius Dreschfeld (Manchester) drew attention to the frequency of tremor as a symptom in functional cases Babinski's reflex sign could not, in his experience, be obtained in hysterical cases of paralysis, but he had observed it in other diseases besides organic paralysis, in a case of scurvy for instance. Nevertheless if on tickling the sole of the foot there resulted extension of the big toe and flexion of the other toes, this, he believed, was absolutely distinctive of organic disease

Dr Buzzard, in replying quite agreed with many of the remarks made concerning Babinski's sign It needed some experience and was sometimes difficult to obtain and different observers did not always succeed in eliciting it.

Mr Hastings Gilford (Reading) read a paper on

Infantilism and Senilism,

accompanied by photographs and cases The word "infantilism had been applied by the French to conditions of generalised delay or arrest of development and the word "senilism" was applicable to the opposite condition of precocious development. These words were, therefore, to development what dwarfism and giantism were to growth Infantilism, like dwarfism, might be due to natural causes It was merely a variation of normal development carried to an extreme degree, and it might be termed "normal infantilism" An instance of this was given in which a girl of 15½ years was of the height of a child of six years, but showed a sexual development like that which is usual at 12 years *Morbid infantilism* consisted of a marked delay of development associated with disease of the thyroid gland, pituitary body, sexual organs, and other parts Infantilism in fact, like dwarfism, might be produced by many causes There was, however, one condition in which the arrest was by far the most marked feature of the case, but for which no cause could be discovered This form of infantilism had received the name of "ateleiosis" It might be distinguished by its abrupt onset without perceptible cause, by conspicuous infantilism with retention of the intelligence, and by a special tendency to delay of development of the sexual system. About a dozen cases had been described The delay of development might be so conspicuous that a man aged 28 years affected with the disease might resemble a boy of six or seven years and might have a skeletal development which was usually met with at 14 years of age. The disease presented a distinct facial type A typical case was described and shown, together with photographs of five others Senilism, like infantilism, dwarfism, and giantism, might be merely a preternatural variation of normal development Instances of this *normal senilism* were given. In *morbid senilism* precocious development was usually associated with premature appearance of the sexual functions and it might be due to acromegaly, to mental shock, or to syphilis Instances of senilism due to the first of these causes were described, and a short account was given of the celebrated French dwarf Bébé After putting on one side cases of normal senilism and those which were the outcome of some known disease a form of senilism still remained to be accounted for This disease, which had received the name of "progeria," had certain distinguishing features Its onset was abrupt, it came on without perceptible cause, it gave rise to senilism of a very conspicuous character, and it did not affect the intelligence. Only two instances of this disease were known, but they were extraordinarily alike The patients strongly resembled each other in height, in form, in facial characters, and in nearly every other respect. They died, one at the age of 17 years from angina pectoris, and the other at the age of 15 years from influenza, combined with general failure of health and other indications of senile decay Their emaciated, wizened, bent, and feeble figures, combined with their baldness, their projecting veins, and an entire absence of elasticity of carriage caused them to present a caricature rather than a picture, of old age Photographs of these and other forms of senilism were shown

SURGERY

Thursday July 31st

Discussion on the Treatment of Tuberculosis of the Testis, Vesiculæ Seminales, Prostate, and Bladder

Mr F A. Southam, Vice President, was in the chair, and in introducing Sir Thomas Myles, the opener of the discussion, congratulated him in the name of the section upon the honour of knighthood that he had received

Sir Thomas Myles (Dublin) said that the subject was a difficult one to deal with and hardly lent itself to picturesque framing The first point was the determination as to what was the precise primary site of tubercle of the genito urinary system. There could, however be no doubt that in the majority of instances tubercle of the prostate and vesiculæ seminales was secondary to tubercle of the epididymis, while that of the bladder was subsequent to that of the kidney Tubercle of the testis was a very important subject and there were two chief schools of thought with regard to surgical treatment—one believed in the early and entire removal of the organ, while the other adhered to partial excision of the affected parts The line of treatment depended greatly upon two queries, (1) as to whether tubercle of the testis was primary and (2) as to whether the disease was a great menace to life He believed that it was primary, in spite of the difficulty of excluding absolutely tubercle from other organs. To justify complete excision of the affected gland it was necessary to show that partial excision was a failure and that primary tubercle of the testis passed commonly to distant organs. Given a nodule of tubercle in the epididymis, and no evidence of tubercle elsewhere, he did not consider that complete removal was justified, but where the testis was destroyed by disease then entire excision was needed if any operation should be carried out. He would classify cases of tubercle of the male genital organs under six headings: (1) those in which one or two small nodules of a chronic type were present in the epididymis and constituted the whole of the mischief; (2) a similar condition but with some slight enlargement of the prostate and vesicles; (3) where secondary suppuration had supervened but there was as yet no evidence of infection of the prostate; (4) a like state, but with consecutive disease of the prostate and vesicles; (5) in which both testicles were the site of a tuberculous deposit; and (6) instances complicated with affection of the lung. In reviewing briefly the surgical treatment of these several classes he laid down the following practical suggestions as his line of action. In the first class partial excision with thorough application of a 5 per cent. solution of formalin gave a very fair proportion of good results. If it failed complete ablation was always open to the surgeon. In the second class he very much doubted whether operative measures ever really did much good. If they were to be of benefit it necessitated the removal of the testis, the vas, the corresponding vesicle, and half, if not the whole, of the prostate. But he could not consider this extensive operation justifiable in most of the cases, for if the disease had spread so far it was probable that it had invaded other organs as well. The third class presented no difficulty—complete extirpation of the testis was the right and proper procedure. The fourth class did not lend itself to operative treatment of a radical nature. In those instances where both testes were involved double castration was advisable, but due regard must be paid to possible mental after-effects. In the last series no operation was admissible. Passing to tubercle of the bladder, it was not by any means always that surgical treatment was an unmixed benefit. Suprapubic cystotomy was so simple an operation as almost to invite the surgeon to undertake it. But there was no true comparison between superficial tuberculosis of the skin and tuberculous ulceration of the wall of the bladder. The former could be scraped and treated with the utmost impunity, the latter only in many cases with grave danger. Partial resection of an infected area with suture he had never carried out, not having dealt with a suitable case. Of tuberculosis of the vesiculæ seminales as a primary lesion he had no personal knowledge. If such a condition did occur excision was clearly indicated. He was afraid that he had been somewhat conservative and pessimistic, but he had candidly stated his opinions, for the opinion of every individual observer was of use in obtaining an aggregate knowledge. He had uttered a warning note against extensive operations, for he felt his responsibility in opening the discussion.

Professor N. SENN (Chicago) admired the paper for conservatism. No doubt in the surgical treatment of tuberculosis of the genito-urinary tract there were well-marked and definite limitations, and this dictum he would pronounce from an extensive experience. With regard to origin, he felt sure that tubercle here was not a primary lesion in some instances. He thought that the classification of cases was good and he was glad to have it. In the descending infections he insisted on the necessity of very careful examination of the urine before operation. The surgeon should also be a physician. Proper hygienic treatment might advisably precede, accompany, and follow operation. The inducement of active phagocytosis was no mean factor in the cure of the affection. Iodoform did all that was desired of it. It was a tissue stimulant, exciting phagocytosis. In simultaneous disease of both testes he did not agree that any radical operation could be performed. In tuberculosis of the kidney he had found that exposure of the organ and the local application of chloride of iodine to the interior of the pelvis and calices of extreme value. He was still hopeful that further patient investigation of tuberculosis would cause the discovery of a remedy which would obviate the necessity of operative measures.

Professor F. VALENTINE (New York) desired to deal rather with the prophylaxis of tubercle. He considered that an ascending infection was probably more frequent than a descending one and he was convinced that the field was prepared by a previous gonorrhœal infection. He therefore urged the need of systematic treatment of gonorrhœa as an important prophylactic measure. He counselled that the urethral discharge should be always stained for the tubercle bacillus as well as for the gonococcus.

Mr. P. MURPHY alluded to four cases of tubercle of the bladder which he had treated by suprapubic drainage, but he confessed that he was not at all satisfied with the results. In tubercle of the testis he advocated incision, scraping, and the application of iodoform.

Mr. JORDAN LLOYD (Birmingham) said that tuberculosis of this area opened up a great field in which much work yet remained to be accomplished. There was yet a want of accurate knowledge in many details. He insisted on the separation of the two systems, one genital and the other urinary, and stated that tubercle appeared distinctly in one or the other and only coalesced at quite a late period. Primary genital tubercle commenced in the epididymis and often altogether apart from preceding gonorrhœa, tubercle of the body of the testis being very rare except as a secondary infection. He believed, however, in primary tubercle of the prostate and of the vesiculæ seminales. It was easy to miss early disease in these latter by careless rectal examination, the finger being carried far too high up. The vesicles should be excised in primary disease. It was important to make a free incision and thoroughly to expose the vesicles before proceeding to enucleation. In primary tubercle of the prostate removal of the same by the perineal route should be adopted. Primary tuberculosis of the urinary system practically always began in the kidneys and there was a descending infection. It was not by any means always that such cases should be submitted to surgical interference.

Sir WILLIAM MACEWEN (Glasgow) agreed with the necessity of recognising that there was tubercle of two different systems, the genital and the urinary, but that they met in the bladder when they had spread far enough. In primary tubercle of the testicle he advised a splitting of the epididymis from the body of the testis, incision of the tuberculous foci irrespectively of any anatomical considerations, scraping and the free application of iodoform, with subsequent suture of the epididymis to the testis proper and closure of the wound without drainage. In cases where the vas was infected he always drew upon the structure by slow traction until he had brought most of its length out of the wound and then divided it and sterilised the cut end. The vesicles, if infected, he removed through the perineum. He had also employed an injection of an emulsion of iodoform into the epididymis without incision. All surgical treatment should be combined with thorough hygienic measures. When the bladder became involved he considered that all treatment was only palliative, with perhaps a cure in a few instances.

Mr. J. RUTHERFORD MORISON (Newcastle-on-Tyne) felt that he was not so pessimistic, perhaps, as some of the preceding speakers had been. Tuberculosis of the genito-urinary tract was not an affection that progressed straight forward to death. There was one symptom, however, which was seldom got rid of—namely, frequency of micturition. He was sure that if it was possible an operation should be undertaken with a view to the removal of the whole affected area. This was impossible when the prostate was involved. He believed that the removal of the testicle even in advanced cases gave relief, for castration secured rest to the corresponding vesicle. There was a great lack of the after-history of cases. He had never seen any good whatever come from the use of iodoform in tuberculosis. It did not cure when applied to tubercle of the skin and he failed to see how it could do so even when hidden in the tissues by injection.

Mr. F. A. SOUTHAM believed that the necessity for double castration often arose, for of 10 recent cases of tubercle of the epididymis in no less than eight was the infection bilateral. He knew that such high authorities as Senn and Watson Cheyne were averse to double castration, but he had carried this out in several instances with the best results. Such a castration for enlargement of the prostate had been followed in several cases by severe mental disturbance, but he had not seen it arise in these instances of tuberculosis. In the former the patients were frequently old men with already senile cerebral changes, but in the latter the patients were usually between 30 and 40 years [illegible] age In one instance he had excised the epididymis alone on one side and the testis and epididymis on the other, with the result that the remaining body of the testis did not atrophy and the patient continued in good health and retained his sexual power He was quite certain that after removal of the tuberculous testis the corresponding infected vesicle had a marked tendency to become shrunken In tubercle of the bladder he was not satisfied by the results of suprapubic drainage

SIR THOMAS MYLES, in his reply, said that he did not consider that gonorrhœal infection of the epididymis had any causal relation to the invasion of the organ by tubercle He quite agreed as to the desirability of keeping the two systems—the genital and the urinary—distinct, but it must be clearly recognised that they became one in the region of the prostate He felt that the removal of only a few inches of the vas was of very little use and strongly advocated its entire excision by extending the inguinal incision

Chronic Pancreatitis Treated by Laparotomy

MR EDMUND OWEN (London) read a paper on this subject based upon the record of two cases The first was that of a man, aged 62 years, on whom he had operated for a septic empyema some years previously The patient was found to be extremely ill with symptoms resembling those of malignant disease of the liver or the head of the pancreas Dr Hale White had also seen the patient and concurred in the probable diagnosis and agreed with the suggestion of an exploratory laparotomy The incision revealed that the head of the pancreas was large and hard and evidently pressing against, and occluding, the common bile duct, thus inducing the jaundice which was present The rest of the pancreas was also greatly enlarged and equally hard This was taken to confirm the adverse diagnosis and the abdomen was closed However, immediately after the operation the patient began to improve and eventually he made a complete recovery The second case was that of a married woman, aged 30 years She had three years previously suffered from septic endometritis For a year she had much flatulence but no vomiting Then jaundice supervened and she lost weight On examination a tender swelling was observed below the ninth right costal cartilage. A provisional diagnosis of impacted calculus was made and an operation was advised This was performed, when it was found that the obstruction was not complete as bile could be squeezed from the gall bladder Further examination showed that the head of the pancreas was almost as large as a fist and that the body and tail were also greatly increased in size The question of establishing a communication between the gall bladder and the duodenum was raised, but in the light of the previous case this was abandoned The patient progressed well and left the hospital at the end of the third week. As to the cause of chronic pancreatitis Mr Owen was ignorant. Were there several forms of the disease, and if so, was one simply catarrhal, and got well spontaneously or after a laparotomy, or was it infection from the duodenum, or was it associated with obstructed jaundice and could not improve without drainage of the gall bladder? Even if it was true that some forms were spontaneously recovered from, yet an exploratory laparotomy might be needed to establish a correct diagnosis and might in some way also effect a cure What should be done with the distended gall bladder in these cases was a matter of difference of opinion.

DR T D GRIFFITHS (Swansea) alluded to the case of a woman who after enteric fever began to have jaundice and loss of flesh Operation exposed a distended gall-bladder without calculi but with an enlarged head of the pancreas He drained the bladder and there was a good recovery in three weeks and the patient remained in good health He questioned the exact cause of the biliary obstruction, possibly it was the inflamed head of the pancreas

SIR THOMAS MYLES said that he had recently had] under his care a woman with a dilated stomach and swelling in the epigastric region, loss of flesh, and severe attacks of pain At the operation the pylorus was found to be free but there was a hard mass in the head of the pancreas, together with a long narrow, distended gall bladder The latter he opened and removed 72 calculi, and closed the incision in the organ with sutures The patient did excellently well He was not at all sure that in some of these cases but that the rest in bed and the semi starvation did not aid the recovery

MR KENNEDY DALZIEL (Glasgow) believed that there was usually a common cause for the jaundice and the pancreatitis, the latter being essentially due to obstruction of the pancreatic duct. He had removed biliary calculi in a case which later showed signs of enlargement of the pancreas, for which he again operated, but did nothing more than the manipulation of the region The patient did well at first but the symptoms recurred and another operation was undertaken, and this time a calculus in the pancreatic duct was discovered and was successfully removed through the duodenum He thought that manipulation might in some of the satisfactory cases cause the dislodgement of a minute calculus from the pancreatic duct.

MR OWEN, in his reply, said that the cases mentioned illustrated three modes of treatment draining the gall-bladder, opening it and closing it immediately, and leaving it untouched. He congratulated Mr Dalziel on his most successful case.

MR RUSHTON PARKER (Liverpool) read a paper on

Experiences in the Extirpation of Tuberculous Lymph Glands during the last 30 years, comprising over 300 Operations

Having seen Professor Billroth perform excision of enlarged tuberculous glands in Vienna in 1871 Mr Rushton Parker began the practice himself in Liverpool in 1872, in which year he performed 28 excisions on 18 young persons, six males and 12 females, from seven to 15 years old, communicating the results to the Liverpool Medical Institution in a paper published in 1873 in the Liverpool and Manchester Medical and Surgical Reports During the 30 years that had elapsed he had performed the operation 318 times on 224 persons, 93 males and 131 females, aged from one and a half to 60 years. The situations operated on were the axilla (15 times), the inguinal glands (10 times), the femoral (once), and the neck in the rest The cases first published by other surgeons, after his own in 1872, were those of Mr T Pridgin Teale from 1878 to 1881 and onwards, and there were some from Mr W K Treves (from 1884 to 1887) who said that he had then practised the operation for years [1] The best account of the class of case requiring operation was that given by Professor T Clifford Allbutt in the reports of the International Medical Congress held in London in 1881 and in the *British Medical Journal* of Nov 25th, 1893 Other writings referred to were those of Mr Teale,[2] Mr W K. Treves and Mr Bertram Thornton,[3] and Dr Keen of Philadelphia,[4] all of whom agreed with Mr Rushton Parker in regarding other treatment as useless trifling Mr Rushton Parker had carried extirpation to considerable lengths and had performed long and difficult operations in many advanced and extensive cases of the disease with the best results in restoration of health and strength, often in previously feeble and delicate persons Though the practice was widely known and adopted it had not received by any means the encouragement that was its due, so he considered that all members of the profession should realise more fully the desirability of its adoption with less delay in the less severe cases, the effect of which would be to diminish the number of neglected and severe cases, and furthermore urged operators more readily and thoroughly to undertake such severe and extensive cases as might occur and not be deterred by attendant difficulties.

MR MCADAM ECCLES (London) read a paper on

The Value of the Imperfectly Descended Testis

He said that almost every instance of imperfect descent of the testis was associated with a patent processus vaginalis testis and often with descent of the viscera into the same Almost all cases of hernia associated with an imperfectly descended testis should be submitted to operative treatment It was thus that the value or non value of the organ which had failed to pass into the scrotum became of great moment and the method of dealing with it of the highest importance The function of a testis was primarily to produce spermatozoa for the reproduction of the species, but there was probably at least one subsidiary use. Without either testis in early life the individual would never acquire the full development of the male characteristics, but although he would have no power to produce spermatozoa, yet if he had testes he would still be capable of acquiring most, if not all, the manly peculiarities Further, although possessing testes, yet the individual might not acquire the male characters showing that these organs were lacking in both their proper functions

---

[1] THE LANCET, July 21st 1888 p 105

[2] Brit. Med Jour Nov 25th 1893

[3] Brit Med Jour vol. ii 1888, p 105, and vol ii, 1889, pp 456 and 544

[4] Brit Med Jour, vol i, 1894, p 160

The testis, therefore, although it might not have reached its usual habitat in the scrotum was yet in many instances of use to the possessor in that it would enable him to develop certain peculiarities which he would not otherwise acquire. The value of the arrested organ in the case of unilateral arrest was not of course so great as it was in the case of double arrest, for a single fully-descended and fully-developed testis was amply sufficient to perform all the requirements of full and complete growth and the development of the male characters. Still, even in these instances a value should be, or should not be, set upon the imperfectly descended organ. On the other hand when the arrest was bilateral the surgeon had very carefully to weigh whether or not the testis had a real value. An examination of a large series of arrested testes removed from adults showed that by far the greater majority had never been capable of forming spermatozoa. There were undoubted instances in which arrested testes had been the seat of spermatogenesis but it would be observed that most of these had been where the testis had not left the confines of the abdominal wall, in fact, it would seem that abdominal retention was by no means a bar to physiological testicular function It was essentially the inguinal testis that was deprived of its power of producing spermatozoa. It would seem that delay in the inguinal canal, in the planes of the muscles of the abdominal wall necessitated failure in the formation of cells capable of giving rise to sperm elements. There were at least three ways in which the inguinal testis might be dealt with when exposed during an operation for an associated hernia. The first was to bring it *down into the scrotum and to fix it there. The second* was to replace it within the abdominal wall. The third was to remove it altogether. If the testis had a real value it should not be removed. It could be safely returned within the abdomen for statistics did not tend to show that there was truth in the statement that the imperfectly descended testis when it lay within the abdomen was more prone to become the site of malignant disease than its fully descended fellow It was on the other hand remarkable that there were few if any definite records of testes which had grown and developed so as to become capable of producing spermatozoa after orchidopexy It would be well that henceforth all such cases should be published.

Mr. **RUSHTON PARKER** stated that in 12 instances in which he had brought down an arrested testis into the scrotum the immediate results had been most gratifying but he regretted that he could not give the after history of the cases. He considered the suggestion of the return of the testis within the abdomen was a valuable one, and he should carry it out in those cases in which it was impossible to perform orchidopexy

Mr **RUTHERFORD MORISON** read a paper on

Incision for and After history of Cases of Removal of Gall stones

He demonstrated by means of diagrams a transverse incision for biliary surgery It was carried completely across the right rectus and opened up very thoroughly the region within which manipulations were necessary In the review of the after history of a series of 43 cases which he had been able to trace he stated that there *had been a* return of symptoms in seven which he referred as being due to either a failure to remove every calculus or to a re-formation of the same. There had been a hernia through the scar in four of the 43 cases

OBSTETRICS AND GYNÆCOLOGY

WEDNESDAY JULY 30TH.

The **PRESIDENT** (Dr D **LLOYD ROBERTS** of Manchester) read his introductory address on the Manchester School of Obstetrics and Gynæcology

Dr A. L **GALABIN** (London) opened a discussion on the Modern Indications for Cæsarean Section.

Professor **MURDOCH CAMERON** (Glasgow) read a paper on 50 Cæsarean Sections.

Dr J **MUNRO KERR** (Glasgow) read a paper on Some Experiences of Fritsch's Fundal Incision in Cæsarean Section.

Several members then discussed the papers

Dr R. **JARDINE** (Glasgow) considered that as a method of treatment in eclampsia Cæsarean section was not to be entertained. In one case he had to perform this operation. The conjugate was two and a half inches and the cervix was not dilated The patient was having fits succeeding each other very rapidly and he recognised that the only chance of recovery which she had was for him to perform Cæsarean section. This he did the child was delivered alive, the fits ceased the albumin disappeared and the patient had practically recovered when some days later pneumonia supervened and she died in 36 hours. At the post-mortem examination no sepsis was found. The speaker agreed with Dr Galabin that Cæsarean section should not be done for placenta prævia, the mortality was very bad 17 per cent. as compared with the ordinary methods of treatment under 5 per cent. He regarded Cæsarean section as the proper treatment for cases of concealed accidental hæmorrhage with no dilatation of the cervix, as in all the cases which he had seen with this condition death had occurred. He thought the statistics of Cæsarean section to be untrustworthy there were so many different factors to be taken into consideration of his own cases, where the operation had been done early and precautions had been taken all the patients had recovered He had never had any difficulty in controlling the hæmorrhage, having always followed Professor Murdoch Cameron's method of using a pessary for that purpose.

Dr **SPENCER** (London) was glad to see that Dr Galabin did not recognise Cæsarean section for cases of impacted ovarian tumours. He considered that the operation had been done for this condition far too frequently, and it was quite easy having brought the uterus out through the abdominal incision, to get at the tumour to remove it, and then to put the uterus back and to deliver with forceps He could not agree with Dr Galabin as to sterilising the patient after Cæsarean section. He thought that the operator had no right to sterilise a woman where the case was one of contracted pelvis only If the patient got pregnant again she could be delivered by Cæsarean section without any extra danger or trouble, and he had lately performed this operation for the third time on the same patient under a local anæsthetic with a good result. He agreed with Dr Galabin that Cæsarean section for placenta prævia was as a rule, quite unjustifiable, but he remembered a case of complete placenta prævia with an dilated os in which the patient had bled to death and he thought now if he had performed Cæsarean section the woman would have been saved. There was one condition that sometimes necessitated Cæsarean section that Dr Galabin had not mentioned—scars in the vagina. As a rule these stretched *or split without any danger* but some years ago he amputated the cervix for malignant disease with the cautery 14 days after labour The patient again got pregnant and at five months the os was quite closed. He let the patient go to full term and then performed Cæsarean section removing the body of the uterus, and the patient was now nine years later quite well. Dr Spencer did not think the fundal incision a good one as there was more chance of the intestines getting adherent.

Mr J **STUART NAIRNE** (Glasgow) thought that a word of warning was needed He considered that Cæsarean section was a very much more serious operation than the induction of premature labour Cases of Cæsarean section could be divided into two classes. First, the poor who provided operators with nearly all their cases The poor were careless and never sought advice till it *was too late for the induction* of labour whereas on the other hand the wealthy would early seek advice and in these cases it was much more a matter of choice whether Cæsarean section or induction of labour should be done Women, as a rule were not so enamoured of Cæsarean section as to prefer this operation with the chance of a living child to induction of labour He had lived long enough and presented so many statistics to this section to know that statistics were very great lies. Lastly when any of his cases went wrong he did not shift the blame on to other people—nurses, &c.—but preferred to carry the battle on his own shoulders.

Dr F W N **HAULTAIN** (Edinburgh) considered the question of borderland cases the most important. Should Cæsarean section or embryotomy be done? Below two and a half inches embryotomy was a very *dangerous* operation but what was the best treatment between three inches and three and a quarter? At three inches embryotomy he regarded as absolutely safe whilst the lowest estimate of the mortality for Cæsarean section was 10 per cent.

Dr **MUNRO KERR** agreed that under two and a half inches craniotomy was very difficult and had a high mortality above two and a half inches he regarded it as a comparatively easy operation. With regard to symphysiotomy there was no difficulty in deciding below three inches it was very dangerous and above three inches it was a safe operation, but in these cases one could not always decide at once, labour must have progressed for some time, and one had to wait to see how the head was moulding Before doing Cæsarean section he always put the patient in Walcher's position and attempted delivery with forceps With regard to the induction of labour in hospital cases he regarded it as a very unsatisfactory proceeding and in cases which he had collected he had found the fœtal mortality to be 40 per cent.

Dr WALTER (Manchester) thought that 30 per cent. or 40 per cent fœtal mortality in these cases of induced labour did not represent the total mortality It was only the immediate mortality and many of the remaining cases died in their first year As regards the uterine incision in Cæsarean section he always selected the longitudinal one instead of Fritsch's the only advantage of which was the easy extraction of the child, and the great disadvantage the greater liability to intestinal adhesions He favoured Cæsarean section for cases of concealed accidental hæmorrhage, with undilated os there was no condition that caused so much anxiety As regards Porro's operation there was a great tendency to lose sight of the fact that it was a very valuable operation for men in general practice, where no proper assistance could be procured

Dr GALABIN, in reply, was astonished that after the great and unique experience which the Glasgow operators had had in Cæsarean section they had not extended the operation to slighter degrees of contraction than two and three quarter inches since in London the operation had been thus extended in the interest of the child and with no ill results to the mothers He agreed with Dr Kerr in his estimate of the fundal incision and also with Dr Spencer as to the greater liability with it to adhesion of the intestines All the statistics that had been quoted with regard to the relative mortality of Cæsarean section and craniotomy coincided with his own, that of Cæsarean section being very much greater He could not agree with Dr Spencer as to sterilisation of the patient. He did not think he had considered those cases where a patient would only allow Cæsarean section to be done under certain conditions If she refused to be sterilised, was the surgeon to give up the case? Certainly not, unless the patient could be handed over to some competent attendant, and even then, in his opinion, he was not justified in so doing He had lately a case of ovarian tumour complicated with pregnancy He advised removal, the patient refused unless premature labour was first induced Knowing it would be more dangerous to leave her to go to term with the tumour he sanctioned the induction of labour and performed ovariotomy 14 days later As regards the small value of statistics which had been discussed by several operators, he himself did not regard as of much value individual statistics but considered generally they were the only evidence he had to go on, and Cæsarean section had been advocated solely on account of these statistics which showed a mortality of about 10 per cent

Professor CAMERON, in reply to Dr Walter, said that he preferred catgut sutures, properly sterilised, to silk, because the latter did not become absorbed.

Dr HERBERT SPENCER read a paper on

Total Abdominal Hysterectomy, especially by Doyen's Method, for Fibromyoma Uteri, with Notes of 14 Cases

He considered the presence of fibroids not in itself an indication for operation Cystic fibroids, large fibroids in young subjects, and fibroid uteri suspected of malignant disease should be removed even when no symptoms were present In other cases operation should be done only when serious symptoms were present or threatened. There was danger of mistaking sarcoma and cancer for fibroids He thought the enucleation especially through the cervix to be the best operation in suitable cases Normal pregnancy and labour might follow If the tumour was not larger than a fœtal head vaginal hysterectomy was to be preferred to abdominal. The three chief methods of abdominal hysterectomy were 1 Supravaginal amputation with extra peritoneal treatment of the pedicle, the mortality of which was slight The disadvantages of this operation were prolonged convalescence and risk of hernia 2. Supra vaginal amputation with intra peritoneal treatment of the pedicle. The disadvantages were bad drainage, danger of hæmorrhage, infection and sloughing of the cervix, leucorrhœa, infection of the stitches, and adhesion of the intestine to the stump, with perhaps obstruction later The growth might be sarcoma or cancer and malignant disease might develop in the cervix. 3 Total abdominal hysterectomy The supposed disadvantages were that it was a longer operation a danger of injuring the ureters, and a danger of vaginal hernia. Only the first objection was a real one if Doyen's method was employed The average duration of his 14 operations was 87 minutes In conclusion, he considered total abdominal hysterectomy superior to supra vaginal amputation and Doyen's method of performing it the best This method he had employed in 12 out of the 14 cases

Mr J H. TARGETT (London) thought the chief reasons for advocating total extirpation were that the drainage was more thorough and the risk of malignant disease occurring in the cervix or part of a malignant uterus being left behind was obviated

Dr GALABIN had not experienced the advantages claimed by Dr Spencer for total extirpation over supra vaginal amputation and he thought there was more danger of injuring the ureter in the former The comparative mortality of the two operations was not very different

Dr WALTER thought it was not easy to decide what was the best method He had performed 38 hysterectomies with one death which had occurred in a case of total extirpation where he had stitched, the roof of the vagina, whereas in these cases he had not done so before His last 10 cases had been by the supravaginal method and the patients had all recovered From what he had heard that day as regards malignancy he should have to reconsider the question. He had noted that the convalescence was more rapid and comfortable in those patients who had had supravaginal amputation

Dr T A HELME (Manchester) had always done pan hysterectomy and had always closed the vaginal roof, except in one case where he did not do so and the patient in this case died He did not think Dr Spencer's results were due to the drainage and he regarded the closure of the vaginal roof as one of the most important steps of the operation

Dr SPENCER replied

STATE MEDICINE

WEDNESDAY, JULY 30TH

The PRESIDENT (Dr JAMES NIVEN, Manchester) opened the proceedings of the section by introducing the discussion on the part played by vaccination in preventing the spread of small-pox and the means by which the maximum advantage of vaccination might be secured to the community He commented on the importance of the subject, and referring to the epidemics which had recently attacked London and those occurring in various large towns in different parts of the country during the past 10 years pointed out the necessity for determining the steps requisite to prevent these epidemics He considered it somewhat of an anomaly that whilst Germany had practically stamped out small pox England, the first country to reap the benefit conferred by Jenner's researches, still suffered from the scourge

Dr E W HOPE (Liverpool) read a paper on

The Precise Part played by Vaccination as carried out in this Country in Preventing Small-pox and the means by which we may hope to Secure the Maximum Advantage from Vaccination.

He pointed out that outbreaks of small-pox invariably revealed the fact that large numbers of people were very imperfectly protected owing to the inefficient manner in which vaccination had been performed, the incidence of the disease always confirmed the truth of a sentence occurring in the report of the Royal Commission on Vaccination, which stated that "the beneficial effects of vaccination are most experienced in those in whose cases it has been most thorough" Vaccination was by far the most certain preventive measure in limiting small pox after it had occurred in a locality The vaccination of some 50,000 people in districts in Liverpool in which small pox threatened to make dangerous headway effectually checked its progress The latter part of the subject involved administrative considerations As vaccination was a protective measure, he asked why it should not devolve on the body which was responsible for the measures adopted to protect the public health—namely, the sanitary authority? The appropriateness of such an arrangement was obvious and above all there would be an immense saving of time, a factor which was of the utmost consequence in repressing an outbreak of small pox, for then the authority which was the first to receive information of the outbreak would have at hand the remedy for its suppression. At the present time this was not so and moreover however admirably guardians and vaccination officers might discharge their duties time was inevitably lost in conveying information. With regard to the operation itself Dr Hope stated that the work of public vaccinators was on the whole more efficient than that of private vaccinators. This no doubt arose from the frequency with which the private practitioner acceded to the request of the parents and inserted the lymph in only one or two places instead of in four On the other hand the private practitioner ought to be entitled to the same payment in satisfactory cases as the public vaccinator There seemed a necessity also for the establishment in proper centres or depots for the provision of lymph which should be active and not as was too often the case, inert. Parliamentary powers for compulsory revaccination were absolutely essential and he would suggest that the most suitable age for the purpose should be 12 years The wilful suppression of information or the knowingly giving of untruthful answers to questions put by the medical officer of health had been the means of depriving persons of the advantages of vaccination or revaccination and had resulted in serious extension of disease He was strongly of opinion that a responsible person who, when applied to by the medical officer or his representative, wilfully withheld information as to small pox or knowingly gave false information should be penalised and in point of fact, Liverpool had sought special Parliamentary powers to deal with such cases. In this connexion he might refer to the recent outbreak at Nelson resulting in 87 cases and six deaths, which undoubtedly had its origin in the mis-statement made by a Liverpool lodging house keeper Though the proposals of the corporation met with opposition from the Local Government Board the principle was embodied in clauses that were assented to by the Committee of the House of Commons and would no doubt pass the House. Many communities would probably seek protection of a similar kind unless the provisions were incorporated in an Act applicable to the whole country

In the animated discussion which followed the reading of Dr Hope's paper Dr E. C SEATON (London) agreed with Dr Hope that private practitioners should receive the same advantages as the public vaccinators but he stipulated that *they should come under equally stringent regulations as to* the method of performing the operation and of returning their results, more especially as they should materially strengthen their main safeguard in the prevention of small pox if only they could rely on perfect primary vaccination throughout all classes of the community Further if it was impossible for the Government to provide all the vaccine lymph employed for vaccination and revaccination he was of opinion that it should at least so control the supply as to guarantee the distribution only of efficient and active material Dr Seaton regretted that the scope of the subject under discussion did not permit him to enter into the question of isolation of first cases in an outbreak, which he personally considered to be one of the most powerful weapons in the fight against small pox.

Dr L J EDWARDES remarked that compulsory vaccination in infancy had reduced the infant mortality but that the adult death rate from this disease was higher now in this country than before the introduction of vaccination by Jenner hence he argued that primary vaccination was insufficient. The Germans had thoroughly grasped this fact and by *means of compulsory* and *repeated vaccination* had practically stamped out the disease Isolation was good but prevention by means of revaccination was better and he would advocate revaccination of school children at the age of 12 years and again later in life, especially in the event of the occurrence of an epidemic. Compulsory powers should also be given to local authorities to revaccinate all individuals living in the vicinity of an outbreak, and finally he would welcome the supply of a vaccine lymph guaranteed by the Government

Dr J G GORNALL (Warrington) mentioned an interesting fact that had come under his own observation which appeared to indicate the possibility of the hereditary transmission of immunity—viz. that the children born of revaccinated parents were much more resistant to primary vaccination than were the offspring of those who had merely undergone primary vaccination During the epidemic of 1882 in Warrington some 14 000 inhabitants including a large number of young female mill hands working in the town were revaccinated and in the course of his work as public vaccinator he had been particularly struck with the difficulty which he so often experienced when vaccinating the children of these women *in obtaining successful* primary vaccination results He was strongly of opinion that vaccination should be completely under the control of the health authorities of a town.

Dr J T C. NASH (Southend) pointed out and emphasised the fact that small pox was almost unknown amongst the successfully revaccinated population He then went on to say that the ordinary vaccine lymph of commerce was extremely uncertain and was sometimes quite inert and he advocated Government control of the lymph supply thus ensuring standard efficiency together with a satisfactory guarantee of its activity

Dr R. C. DRYSDALE (London) referred to the recent epidemic of small pox in London and in contrasting this with the conditions that obtained in Germany he stated that the mortality in the latter country for the year 1898 only amounted to 15 out of a total population of 45 000 000. He was certainly in favour of compulsory revaccination as the most powerful weapon at their disposal against this essentially preventable disease.

Dr N E. ROBERTS (Liverpool) said that the main question *before them was whether they could recommend some* legislation in connexion with revaccination for the benefit of the public at large, for he supposed that they were all of one mind that revaccination was absolutely the best thing, both for the individual and for the State.

Dr THEODORE DYKE ACLAND (London) remarked that he was in favour of the view that the average Briton was much more easily led than driven and he considered that they would get far better results if they showed that their own position was absolutely impregnable, and so left no loophole for people to escape from the conclusion that the individual was greatly benefited by revaccination. In fact, the most important work for the medical profession at the present moment in this connexion was the education of public opinion. He then moved the following motion

That inasmuch as there is strong evidence to show that the effect of *infant vaccination has very largely lost its effect after* 10 or [illegible] years it is desirable that all children should be revaccinated at the age of 12 years.

The PRESIDENT expressed his distinct conviction that compulsion was necessary At the same time the English people would not be coerced, and he quite agreed with Dr Acland that it would be unwise to drive the objectors too far and he would, therefore, leave a loophole for the escape of fanatics or conscientious objectors. Such a loophole was at present in existence by reason of the provision for the conscience clause in the last Act

Dr J M RHODES (Didsbury) seconded the motion and while he agreed that a loophole should exist he argued that it should be made as small as possible People would strongly object to a man bearing a lighted torch walking about in a crowd yet many of those who refused to be vaccinated were quite as dangerous to the public safety

On being put to the meeting the motion was carried unanimously

Dr RHODES submitted a further motion —

That in the opinion of this section of the British Medical Association the duties appertaining to vaccination and revaccination should be *transferred from the* Poor-law authorities to the county [illegible] authorities, as those responsible for the public health.

In supporting this motion he stated that he did not believe that the Poor-law guardians constituted a proper authority to administer the Vaccination Acts Further the profession and the guardians were not always in perfect agreement although on this particular question agreement was absolutely essential His own opinion was that the administration of the Act should be placed in the hands of the magistrates but if this were impracticable it certainly ought to go into the hands of the local sanitary authorities The Association of Poor-law Guardians had [illegible] expressed its approval of such a change

The motion was seconded by Dr [illegible] and Dr EDWARDES in supporting it urged that it was extremely desirable for the efficient working of the [illegible] this motion that a central authority should be established in London Such a measure was an imperial one [illegible] required to be carried out in an imperial manner [illegible]

On being put to the meeting this motion was also carried.

Dr C [illegible] (Le[illegible]) read a paper on

What are the Factors Influencing the Production of [illegible] and How can they be Reduced to a Minimum?

He stated that return cases of scarlet fever were due to infection carried by patients [illegible] home and must therefore be regarded as essentially a "hospital phenomenon" The infective influence arising from the discharge of patients from hospital might persist for at least six weeks On the other hand, analogous cases rarely occurred after the discharge of cases treated at home. The fatality of return cases, it should be noted, was above the average Return cases, however, could not be considered as due to premature discharge, for it was the common experience of all hospitals that mere increase of length of stay in hospital would not prevent their occurrence, and in point of fact there were grounds for fearing that prolonged residence in an infected atmosphere predisposed to their occurrence, even if it were not actually productive of them Neither did his experience support the supposition that return cases were in any way connected with protracted desquamation of the cuticle Dr Millard mentioned that the principal clinical conditions associated with the occurrence of return cases were discharges from the ear and nose, and he stated that some observers had suggested that these discharges were to some extent a hospital product. The ultimate causation of return cases might therefore be ascribed to inhalation of an infected atmosphere leading to the accumulation of infective matter in the nasal cavity, which was discharged after the patient's return home, and also in some cases to a residence in an infected atmosphere interfering with the elimination of infection by the patient and thus retarding recovery Dr Millard then suggested that the most effectual means for the prevention of return cases consisted in (1) isolation of convalescents from acute cases, or cases still infectious, prior to discharge from hospital, and (2) the substitution of an ordinary house for a hospital and separate rooms for large wards In conclusion Dr Millard pointed out that in Manchester in 1901 return cases neutralised 48 per cent. of the advantage gained by hospital treatment in preventing secondary cases.

The PRESIDENT did not consider that the occurrence of return cases could be held to outweigh the great advantages of isolation hospitals in preventing the spread of infectious disease

Dr MERVYN GORDON, who showed a series of lantern slides, held that the prevention of return cases was best attained by rendering all discharges innocuous by the careful use of suitable disinfectants, rather than by keeping the convalescents in hospital till all discharge had stopped.

After a few remarks by Mr C H TATTERSALL (Manchester), Dr HOPE stated that the proportion of return cases in Liverpool was small, whilst the mortality of scarlet fever patients treated at home, even when the attack appeared to be a mild one, was higher than was that of the hospital treated cases, including those of marked severity

---

PSYCHOLOGICAL MEDICINE

WEDNESDAY, JULY 30TH.

President's Address

Mr G W MOULD (Cheadle) dealt in his presidential address with the question of recent advances in the housing and treatment of the insane and especially with the employment of the system of detached blocks or "villas" for patients He paid a high tribute to the memories of Dr Bucknill and Dr Hack Tuke who by their work laid the solid foundations on which had been erected the subsequent achievements of Henry Maudsley, Crichton Browne, Clifford Allbutt, and others, in psychological medicine The late Professor Charcot was a prominent figure at the last meeting of the section in Manchester 25 years ago and took an active part in contributing to the papers and discussions in nervous and mental disease on that occasion Professor Virchow was another prominent figure among the visitors during the same year and contributed not a little to stimulate pathological investigation and research In 1858, when Mr Mould began to practise in mental diseases, heroic dosage of drugs and heroic therapeutics, such as the use of the whirling chair and the administration of large doses of tartar emetic, were largely in vogue in asylum practice. Much of this had, however, died away with the advancement of knowledge. The housing of the insane had always been a matter for serious consideration and in the Manchester Royal Asylum at Cheadle he had, since 1862, adopted the plan of distributing the majority of the patients and of treating them in separate cottages or "villas" apart from the main building This plan of housing the insane was now being adopted extensively both in Europe and America and it had at present the support of the most advanced and enlightened psychiatric physicians He was glad to see such a large and representative assembly of alienists present from all parts of the kingdom and hoped that the papers and discussions of the section which were to follow would prove a success A vote of thanks was unanimously accorded to the President for his concise, interesting, and practical address

Sir JOHN SIBBALD, M D, Commissioner in Lunacy for Scotland, opened a discussion on

The Care and Treatment of Persons of the Poorer Classes in the Early Stages of Unsoundness of Mind

His proposal was to establish wards in general hospitals for the treatment of persons of the class just referred to The suggestion that such wards should be established in Scotland was recently submitted to the profession in Edinburgh by Dr J MacPherson and himself The authorities of the public asylums had for years been most earnest and successful in making their institutions more and more efficient as hospitals for the insane. But persons who had been patients in asylums were, whether justly or not, handicapped in their future careers after being discharged as recovered The friends and relatives of patients therefore felt a natural reluctance to avail themselves of the benefits to be obtained in asylums. A more important reason for wishing that wards for patients in the incipient stages of mental disease should be provided in general hospitals was that patients suffering from such incipient illness could not be certified as insane and received into asylums, and although they might properly be received into general hospitals, yet as a matter of fact, they seldom were There was, it was true, in most hospitals a special emergency ward where patients suffering from acute alcoholic or other form of mental excitement or delirium were received, and in some hospitals also a few cases with symptoms of mental disorder were to be met with in the ordinary medical wards But it was not the general rule, and, in fact, it was quite exceptional to receive or to admit patients with mental disorder, and even in those hospitals where such patients were freely admitted there was no provision to admit all mental cases which it was wished to provide for The present position of the matter might be summed up in two propositions first, persons suffering from mental disorders in their early stages were not, and under British lunacy law could not be, provided for in asylums, and, secondly, such patients were at present, as a rule, unprovided with hospital treatment of any kind. All that he desired general hospitals to do was to do for mental disease in its early phases what they did for disease in general—viz., to receive patients of the poorer classes who suffered from incipient mental disorder and who could not be properly treated under the conditions usual in the homes of the poor but could be suitably treated in general hospitals. As far as facts enabled him to judge, he thought that if such "mental wards" were established in general hospitals they would not fail from lack of inmates Of course, there might be difficulties at first in deciding how certain cases—especially those of temporary mental disorder due to alcoholism—should be dealt with, but such difficulties were not insuperable The length of time a patient with incipient mental disorder might remain in a general hospital was a very important point and he was of opinion that it should not be longer than six weeks Such a restriction was necessary, if for no other reason, to prevent the wards being used for any except incipient cases At the meeting of the Medico-Psychological Association held recently in Liverpool, Dr Nathan Raw stated that out of 3129 cases of mental disorder which had during the past five years come under his survey at the Mill road Infirmary, Liverpool, no less than 1006 were discharged as recovered, although such patients were prevented by statute from remaining in the wards longer than 17 days, and he (the speaker) understood that Dr E S Reynolds had had similar experience in Manchester, and Mr J Carswell in Glasgow Such facts were significant, though to weigh their significance quite accurately it was requisite to know the proportion of acute alcoholic cases among the patients treated. He suggested that it was desirable that the mental wards which he proposed for general hospitals should be in charge of physicians who had devoted their special attention to the care and treatment of mental disease, and he thought that the proportion of cases for which such hospital treatment was desirable was not small. Success usually attended the treatment of most forms of incipient mental disease by skilful medication, diet on approved therapeutic principles, prolonged rest in bed and continuous nursing night and day, all of which could be well carried out in a general hospital He thought that it was an excellent practice to employ female nurses in such mental wards, as they were employed in other wards of general hospitals In an interesting paper on the pyschiatric wards of the Copenhagen Hospital published in the July number of the *Journal of Mental Science* Professor Pontoppidan furnished valuable evidence founded on an experience of 14 years in support of the practice of employing female nursing in the class of cases alluded to, and already this view was gaining hold in the asylums of Great Britain. There was at present in the air the rival proposal of providing separate special hospitals—institutions apart from general hospitals and public asylums—for the reception and treatment of incipient cases of mental disorder An insuparable objection to this scheme however was that by whatever attractive name such hospitals might be designated they would be classed by the public as "asylums" and the patients whom it was wished to benefit would accordingly shrink from entering them. The importance of avoiding everything which was suggestive of, or connected with asylums in the public mind was indeed so great that if such wards as were proposed were established in general hospitals it would be essential that their structural arrangements and their mode of administration should be such that while fulfilling all the requirements for mental cases they should in no way be obviously distinguishable from the ordinary medical wards. Such wards would offer exceptional facilities to the medical student for gaining a practical acquaintance with mental disorders in their early and incipient stages. Patients seen by the student attending the usual course of clinical lectures for a term in a public asylum were not such as he would be called upon to treat in general practice. What the student and the general practitioner required was to learn to distinguish and to treat the various forms of mental disease at their incipient and early stages and before they had advanced sufficiently to need certification and sequestration in an asylum With such knowledge the practitioner would be prepared to render important services to his patients at the most critical period of their lives, when the mental life and capacities of the latter hung as it were, in the balance But above all considerations there rose the supreme fact that the establishment of such wards would give an opportunity for the special treatment of mental diseases at the time and stages when they were most amenable to treatment and when the prospect of recovery seemed to be the most hopeful.

Dr D YELLOWLEES (Glasgow) in the discussion which followed the above expressed his appreciation of the temperate tone of the paper and stated that non certifiable mental ailments such as hypochondriasis hysteria and other like conditions were far more frequent in the social grades above that of the poor who as a rule, had to work for their living and did not develop such neuroses or psychoses He thought that removal from home, open-air country life, with suitably prescribed rest and exercise and the needful medical treatment were the best modes of procedure. He therefore was in favour of separate and special hospitals for such patients, situated preferably in the country away from noise dust, and smoke.

Dr J WIGLESWORTH (Rainhill Asylum) thought that a mental department attached to large general hospitals would be an advantage for patients whose mental disorders originated from acute toxic sources and who tended to recover within two or three weeks of the first on et of mental symptoms For other cases—and they formed perhaps the majority—he was of opinion that special mental hospitals would prove more useful.

Dr OSCAR T WOODS (Cork) was of opinion that the number of cases which would seek admission into the mental wards proposed to be established in general hospitals would be small He would welcome any scheme that tended to promote the cure of mental disease in an early stage, as it was a fact that in the class of ca es admitted to asylums the recovery rate was very low and it could be maintained as a general proposition that no more than 5 per cent. of the population of our asylums were curable

Dr DAVID BOWER (Bedford) generally concurred in the proposals put forward by Sir John Sibbald but thought that out-patient departments should be established at existing asylums and that the resident physicians should be allowed to see patients in consultation outside the institutions to which they were attached.

Dr ROBERT JONES (Claybury Asylum) was in complete sympathy with the aims and objects put forward by Sir John Sibbald. He favoured the establishment of special hospitals for the reception of early cases of insanity in or near London as these could be made centres of clinical teaching also

Mr JAMES STEWART (Clifton) dwelt upon the odium attached to the words lunatic and asylum" by the general public and thought that the term 'asylum should be discarded for the term "hospital for mental diseases.

Dr A. T SCHOFIELD (London) said that his attitude was one of discontent at the unsatisfactory state of psychological medicine in regard to early diagnosis and the treatment of incipient cases owing to the want of opportunities for instruction in this matter both for the general practitioner and even for the neurologist.

Dr W LLOYD ANDRIEZEN (London) said that the question was one of deep scientific and social importance. The present attitude of the specialty was one of reaction from the despair entertained for long and now confirmed yearly concerning the relative incurability of cases in asylums the true recovery rate being in fact, about 10 per cent. or even less He thought that out-patient clinics and wards for the reception of early and suitable mental cases should be provided in general hospitals and he believed that for a large class of cases institutions on the farm colony system should also be provided.

Dr T SEYMOUR TUKE (London) thought that the reduction of incipient insanity would be a boon and would tend to reduce the ratio of criminality in certain respects. He looked with favour on special wards or special hospitals which no doubt would arise in accordance with the needs of the community

Dr WILLIAM DOUGLAS (Leamington) strongly supported the proposition of establishing wards for mental cases in general hospitals.

Mr G E. MOULD (Sheffield) said that he had no hesitation in supporting Sir John Sibbald s scheme as his experience in the mental out-patient department of the Sheffield Royal Hospital bore out the views propounded by Sir John Sibbald

Dr FLETCHER BEACH (London) spoke favourably of the scheme of having an out patient department for receiving and treating certain forms of minor mental disorder as Dr Henry Rayner had done for years at St. Thomas s Hospital As regards the admission and treatment of such cases in hospital wards he thought that there was more to be said for than against it

Dr ALEXANDER BRUCE (Edinburgh) stated that his experience had led him to sympathise strongly with the scheme propounded by Sir John Sibbald.

Dr E. S REYNOLDS (Manchester) strongly supported the view that general hospitals should contain wards for mental cases and said that his experience in Manchester indicated that undoubted benefit would follow such a scheme

Dr JAMES SHAW (Liverpool) was in favour of the reception of patients into the mental wards of general hospitals and thought that a further scheme of convalescent homes connected with the former would be worthy of consideration.

The PRESIDENT made a number of general observations on the importance of the subject of Sir John Sibbald s paper and said that on the whole the scheme deserved encouragement and sympathy The discus ion then concluded.

PHYSIOLOGY AND ANATOMY

WEDNESDAY JULY 30TH

Dr D BERRY HART (Edinburgh) read a paper and gave a demonstration on

The Development of the Human Genito-Urinary Organs

After briefly reviewing and criticising the existing view as to the origin of the vagina, uterus and Fallopian tubes he passed on to give his opinion as to the part played by the Müllerian and Wolffian ducts in the development of these organs He considered that the Wolffian duct was entirely ectodermal in origin and that the Fallopian tubes uterus and upper two-thirds of the vagina were formed from the fused [illegible] hi d of the vagina was formed from [illegible] d Wolffian ducts The hymen, [illegible] rom the Wolffian duct by the coalescence of bulbous proliferations of its cell while the prepuce of the clitoris and penis was formed as a solid ingrowth of surface epithelium which subsequently underwent central desquamation to form the lumen. He pointed out that a similar mode of formation occurred in the case of the sweat glands, the anus, the amnion, the urethra, and the like The remarks were illustrated by numerous drawings, photographs, and lantern slides

Professor A M PATERSON (Liverpool), after thanking Dr Hart for his interesting paper, said that he was unable to accept the view that the Wolffian duct was of ectodermal origin, he regarded it as a mesoblastic structure

Professor ARTHUR ROBINSON (London)' found himself unable to accept the view of the development of the lower part of the vagina which Dr Hart had propounded until Dr Hart was able to explain how it was that, if the vagina was formed by the union of the Wolffian ducts and uro genital sinus the bladder opened at the anterior margin of the vagina and not into it

Dr PETER THOMPSON (London) pointed out that the nerve supply and general morphology of the flexor group of caudal muscles in the lower mammalia did not support the view that the pubo coccygeus was primarily associated with the lower end of the genito urinary tract

Dr HART briefly replied to the various speakers

Mr F A. BAINBRIDGE (London) read a paper on

The Relation of Metabolism to Lymph Formation

After pointing out that lymph formation might be considered in its relation either to the blood or the tissues he passed on to deal with the relation which existed between tissue activity and lymph formation He said that in the case of the sub-maxillary gland, the liver, and the pancreas increased secretion—i.e, increased metabolism—invariably lead to increased lymph formation The possibility of its formation being due to altered capillary pressure and permeability was excluded and it seemed probable that the lymph was formed as a direct result of the metabolism He supposed that during metabolism crystalloid bodies were formed in the tissues, these passed by diffusion into the lymph, raised its osmotic pressure and therefore attracted water from the blood, the result being an increased flow of dilute lymph

In the discussion that ensued Professor W H THOMPSON, Dr J S EDKINS (London), and Professor W STIRLING (Manchester) took part

Professor ROBINSON showed a Hand in which there was congenital absence of the right middle finger The history of the case, he said was interesting as the mother prior to the birth of the child had frequently foretold some deficiency of this particular member Professor Robinson pointed out that the maternal impression could have had no effect on the production of the malformation, as dissection showed that the flexor tendons to the missing finger were present though fused to those of the index finger, and these tendons were developed long before the maternal impression existed

Professor STIRLING made some brief observations on Parturition in the Guinea pig After pointing out the smallness of the pelvic outlet and the immoveability of the bones in a non pregnant animal and the comparative large size of the newly born animal he demonstrated how in the pregnant guinea pig the symphysis pubis became widely separated and the bones freely moveable.

Professor PATERSON brought forward a communication on the Development of the Shoulder Girdle in Mammals

---

PATHOLOGY

THURSDAY JULY 31ST

Professor G SIMS WOODHEAD (Cambridge) opened the discussion on

The Place of Bacteriological Diagnosis in Medicine

with a paper in which he considered especially the bacteriological diagnosis of diphtheria and referred briefly to the bacteriology of cholera anthrax, typhoid fever, and other diseases His experience in regard to diphtheria extended to nearly 30 000 examinations in 12 172 patients during the past three years Careful examination satisfied him that the value of such examinations was rather under than over estimated The clinician and the bacteriologist must work together and if they did the errors in diagnosis were reduced from 20 per cent. to 5 per cent. in diphtheria cases He found that the clinical and bacteriological diagnosis agreed in over 73 per cent of cases In 26 per cent no bacilli could be demonstrated, but he considered that the clinical diagnosis was accurate in more than the 73 per cent., for there was difficulty in obtaining information concerning many of the specimens sent for bacteriological investigation It was very important in making a diagnosis to obtain accurate information as to the conditions under which the swabs were taken and in which the patient existed Diphtheria bacilli might be present in normal throats as, for instance, in those of nurses attending diphtheria hospitals, but if the general health was low or if an attack of catarrh occurred the diphtheria would surely develop Again, in children with laryngeal diphtheria the membrane might be inaccessible to the swab and no culture be obtained In cases of diphtheria *in extremis* he had sometimes got a negative result. In these cases the diphtheria bacillus after having done its work seemed to be ousted from its position by putrefactive bacteria late in the case. In laryngeal diphtheria 68 per cent were unsatisfactory bacteriologically, no bacilli having been found in severe cases followed by paralysis There was a great necessity for repeated examination to elucidate the diagnosis and to direct the after treatment In 66 patients a negative bacteriological diagnosis was obtained and this was followed in another attempt by a positive diagnosis of diphtheria bacillus In many cases patients were dismissed from hospital with the diphtheria bacillus still present. Professor Woodhead considered that the patients should be isolated until the bacilli had entirely disappeared. Attention should be paid to the complicating organisms which were found along with the diphtheria bacillus and their effect on the mortality From his figures Professor Woodhead found that the highest mortality obtained where the typical long diphtheria bacillus was present and that the mortality diminished as this form was departed from. This left out the very virulent forms in which the bacillus had a short wedge shaped form In pure cultures of the long bacillus the mortality was 21 4 per cent, where the long and short bacilli were present about 20 per cent., when short and irregular forms a little over 18 per cent, in irregular forms alone 17 3 per cent., and in short forms alone 3 3 per cent In mixed infections when the streptococcus was present with the diphtheria bacillus the mortality was 24 5 per cent. with the long bacillus and 10 4 per cent. with the short The most fatal form of diphtheria was that in which the pathogenic organisms were mixed with staphylococci, in which the mortality was 42 5 with the long diphtheria bacillus and 11 9 with the short The mortality was always higher in mixed infections In scarlatinal cases the lowest mortality was with diphtheria bacilli alone. Professor Woodhead considered that the period of isolation after diphtheria should be extended as every case of diphtheria was a centre of infection until the bacillus had disappeared from the throat He entered in detail into the length of time he had found the bacillus still present after diphtheria. The presence up to eight weeks was very common. From two to nine weeks was the time in which they might be present but there were some exceptional cases in which this period was exceeded

Professor D J HAMILTON (Aberdeen) congratulated Professor Woodhead on his elaborate and accurate paper His own observation bore out every point upon which Professor Woodhead had insisted There was always a difficulty with the pseudo-diphtheritic bacillus but the cases in which this arose were few The only method of differentiating accurately between this and the true bacillus was by inoculation experiments The mistakes in diagnosis of diphtheria bacillus in his practice did not exceed 4 or 5 per cent.

Major R. H. FIRTH, R.A.M C, said that some years ago too much reliance was placed upon the bacteriological diagnosis but its relative value was now more clearly defined. No opinion could be given in a hurry in regard to diphtheria water &c He strongly insisted that a diagnosis could not be made in 24 hours and refused to give an opinion under 10 days The danger signal of cholera in water was the presence of a large number of fluorescent vibrios Previously healthy waters in which these vibrios suddenly appeared were certain to cause an epidemic of cholera in a few weeks. He had never seen a typhoid bacillus recovered from a sample of water but bacilli coli communes and other bacteria were found and in these cases the water should be condemned Streptococci were always present in polluted waters and if found indicated a recent contamination Taken alone, the streptococci were not sufficient to condemn the water but when combined with bacillus coli communis the water should be rejected

Professor S. DELÉPINE (Manchester) expressed his thanks to Professor Woodhead for his valuable address and a general agreement with his statements Some differences in the results obtained in Manchester were chiefly due to the administrative methods and class of cases dealt with since 1893 he had insisted upon the importance of the bacteriologist not taking upon himself any administrative responsibility The medical officer of health *with the assistance of the clinician and the bacteriologist*, must remain the only person responsible for diagnosis upon which administrative measures were based. In relation to typhoid fever it was important to remember that negative results obtained before the seventh eighth, or ninth day were not to be relied upon as conclusive, although positive results might be accepted Professor Delépine discussed the advantages of a modification of the Widal method which he had introduced.

Dr W G SAVAGE (Cardiff) discussed the relationship of bacteriological diagnosis to state medicine Complete appliances were necessary for accurate work and the difficulties of bacteriological diagnosis had increased with more extended knowledge. The value of bacteriology in state medicine fell under the following heads (1) the examination of material from suspected cases of diphtheria, &c. (2) the examination of foodstuffs, especially milk and meat (3) the systematic examination of water supplies, and (4) the special investigation of threatened outbreaks of plague, anthrax, &c.

Dr G LESLIE EASTES (London) insisted upon the necessity for caution in the interpretation of the results of bacteriological analysis and pointed out some of the difficulties which assail the bacteriologist. He illustrated the latter from his experience of the Widal reaction.

Dr G NEWTON PITT (London) who presided, referred to the clinical aspect of bacteriology He had seen several cases in which the diphtheria bacillus was present, but there was no inflammation of the throat or larynx How were these to be treated? He did not agree with Professor Woodhead's opinion that they should all be isolated and he illustrated the difficulty in applying this measure to large schools.

Dr R. M KALAPESI (Bombay) said that in India typhoid fever assumed peculiar types, which were very difficult to diagnose even at the end of the second week. Since the Widal reaction had been introduced these cases were readily diagnosed. He referred especially to cases of so-called remittent fever many of which were found to be typhoid fever Again cases of Malta fever were found in patients who had never been out of Bombay and many of these were proved to be typhoid fever by the Widal reaction

Professor SIMS WOODHEAD reserved his reply

Major R. H. FIRTH R.A.M.C and Major W H. HORROCKS, R.A M C communicated a paper on

The Viability of the Enteric Bacillus in Soils and in Fabrics.

They said that although water was the universally recognised medium by which enteric infection was spread there were other means by which enteric fever might be disseminated. Of the less commonly recognised factors recent experiences in India and South Africa had directed attention to the soil and fabrics as sources of contagion. After discussing the diagnosis of the typhoid bacillus and the methods used in the investigation they concluded (1) that there was no evidence that the typhoid bacillus in soil could increase or grow in different directions (2) that the enteric bacillus could be washed through at least 18 inches of closely packed soil by means of water (3) that the bacillus survived in soil for varying periods sometimes as long as 74 days (4) that the enteric bacillus could survive in soil whether polluted or not (5) that its survival was dependent upon the amount of moisture present (6) that the bacillus could be recovered from fine dry sand after 24 days but if the sand was kept moist the bacillus could not be recovered after the twelfth day probably from being washed down into the deeper layers (7) that the bacillus rapidly died out in peat (8) that from ordinary soil kept damp with rain water the bacillus could be recovered on the sixty seventh day with dilute raw sewage on the fifty fourth day with dilute sterile sewage on the seventy fourth day and that in similar soil the bacillus at once disappeared from the surface layers after heavy rainfall (9) that infective material could be readily carried from dried soil and sand by air currents; (10) that the bacillus was recoverable from khaki drill on the seventy fourth day, from khaki serge on the eighty-seventh day and from blue serge on the seventy eighth day and (11) that ordinary house flies could convey infective matter from excreta or other polluted material to objects on which they walked rested or fed and that such infective matter appeared to be attached to their heads, legs bodies, and wings but the bacillus did not pass through their digestive tract.

OPHTHALMOLOGY

WEDNESDAY JULY 30TH

Dr CHARLES EDWARD GLASCOTT opened the sectional meeting with an expression of his deep regret at the absence from the chair of Dr David Little owing to indisposition. He welcomed the gathering to Manchester thanked them for their interest, and believed that in the Royal Eye Hospital would be found something of interest to note

Mr R. MARCUS GUNN (London) opened the discussion on

Functional Derangements of the Eye (so-called Hysterical)

At the outset he said that he intended to confine his attention to functional or hysterical amblyopia, a sufficiently wide subject to do any justice to The clinical observer was confronted with the difficulty of separating hysterical loss of vision from malingering In both were found (1) loss of vision in one or both eyes, partial or complete, usually of sudden onset (2) absence of ophthalmoscopic evidence of disease in the optic nerve or in the fundus to account for the visual failure and (3) absence of any impairment in the reaction of the pupil to light Further in functional cases they observed mostly that the visual loss and associated symptoms and the after history of improvement or recovery did not correspond to the product of any known organic lesion or disease. *Malingering* would always be a difficulty especially when advantage might result to the patient on claims for damages arising out of the association of the amblyopia with accidents or in the shirking of disagreeable duty here one must be guided to some extent by impressions drawn from the patient's general attitude Functional amblyopia was more common in females and it was in these cases particularly that hysteria and deceit were likely to overlap or to merge. There were certain recent statements to the effect that a true hysterical one-eyed blindness might co-exist with good binocular vision that an eye unable to see alone could see in partnership with the other If this were true there must be a double distinct central representative in consciousness (1) of each eye by itself and (2) of both eyes together and one must here suffer and not the other That *fusion* was distinct from double vision was certain but more than this he could not believe, but rather held the older simple view that binocular vision *plus* one-eyed blindness meant *duplicity* truly but of another sort. A variety of simulation occurred commonly in young women who complained of recent failure of sight in both eyes and who did not assign any cause or complain of pain The vision equalled about [illegible] but was improved greatly by a weak plus lens and still more so on adding thereto the compensating lens. This could only be feigned" even suggestion could not be called in to explain a supposed cure Recently there had been described cases of one-eyed functional amblyopia with mydriasis of the same side he would like to be satisfied (1) that the inequality of the pupils did not pre-exist and (2) that there was no associated loss of accommodation as might follow the use of a mydriatic It was said with these cases that there might be associated spasm of accommodation in the amblyopic eye, but it was not stated if this coexisted with the mydriasis—a strange combination—or with myosis. On the general question complete double amaurosis was rare he had seen one following mydriasis this was cured by suggestion. More commonly the loss of sight was complete or partial in one eye only here the reaction of the pupil to light was of greatest importance lest after contraction to light there should be with continued exposure a secondary dilatation a phenomenon associated with the amblyopia of retro-bulbar neuritis—a disease not infrequent in young hysterical women as a precursor of insular sclerosis. Rarely functional homonymous hemianopia might occur this had been denied but he had seen cases thereof. In one case a female aged 33 years there was such a condition following on a series of marked sensory manifestations yet on objective examination no abnormal condition could be found. The functional condition [illegible] of simulation was that limiting of visual field associated with functional hemiplegia and hemianæsthesia. Here the visual defect was more commonly discovered by the examining surgeon, the loss of field was noted to be greatest upon the side corresponding to the side of motor or sensory defect. It had been said that in similar cases the field for red was greater than that for white or blue, recently he had examined for this without success In a large class of cases the amblyopia was definitely associated with an injury, one producing a considerable degree of shock, Mr Gunn detailed three such cases wherein a railway accident, a fall from a horse, and a pin prick were the exciting causes, producing great diminution of vision and from which recovery was complete Of the nature of nerve injury underlying these hysterical manifestations they were in the dark, some might be associated with simulation, others with an early obscure manifestation of a real organic disease, it was certain that some hysterias terminated in insular sclerosis There might in general be a disturbance of association fibres betwixt higher and lower centres, the centres were capable, the reception was good but the consciousness thereof was diminished Change of scene and friends afforded the most certain lines of treatment. Judicious dietary, assafœtida, and faradism were of use.

Mr W T **HOLMES SPICER** (London) said that as to the question of helical fields in hysterical amblyopia it would be interesting to know whether Mr Gunn had tested the visual field of one eye to complete exhaustion and then observed whether the other field was also similarly contracted He believed it was so, and if so it would go to prove that the lesion was not retinal but was central as Mr Gunn had suggested As to one eyed mydriasis he had met a case lately a girl who had defective sight in one eye of sudden onset in which mydriasis was present No cause could be found for the mydriasis, the patient was carefully watched in the hospital and hysteria was suspected. After about a month very slight pallor appeared in the optic nerve showing the case to be one of retro-ocular neuritis

Dr A. **MCGILLIVRAY** (Dundee) said he had seen very few such cases. They must be exceedingly rare in Scotland.

Dr A. H **GRIFFITH** (Manchester) felt the question turned on whether they should judge the subject as patient or culprit, if as "patient," was the cause organic or functional? He had no doubt as to their occurrence, he had seen them in Manchester and he felt an inclination to belief in an organic basis in many of them

Mr R. W **DOYNE** (Oxford) remarked on the peculiarity of a visual field of greater area for red than blue or white, it was contrary to all law Also, he would call attention to the occasional overlapping of traumatic functional amblyopia by toxic amblyopia, which was well set forth in a case of his where the patient in brooding over his "accident" blindness smoked himself genuinely blind, as the scotoma showed

The **CHAIRMAN** said that evidently his country was not so level headed as Scotland, for he had seen such cases from fright and fear of punishment In one case a man, who subsequently got quite well, obtained £500 damages for his injury, the shock arose from the vagaries of a petroleum lamp, in another it followed enucleation He would also remark on the danger of missing a toxic amblyopia, for sometimes this form was marked in one eye only

Mr **GUNN**, in reply, said he agreed that functional disorders were often opposed to physiology He had never seen red fields greater than white but the idea was that under peculiar conditions a red object might strike where a common white colour was ignored He thought that traumatic functional amblyopia might occur, but agreed that it was to be viewed with great caution, especially where questions of "damages" came in.

Dr **KARL A. GROSSMANN** (Liverpool) read a paper on a case of

Ivory Exostosis Operated upon and Observed during 18 Years

He had made an earlier communication of this case[1] The disease apparently commenced in 1884, when the man was 24 years of age There protruded below the inner half of the right eyebrow a large, round fixed, very hard swelling which filled this region of the orbit The eye was pushed down and out towards the zygoma, its movements were free, but the lids closed over it with difficulty There was considerable conjunctivitis, the optic disc was red, and the retinal veins were dilated. The vision equalled $\frac{10}{40}$ The left eye and orbit were normal save for a small hard knob of the size of a cherry stone above the inner canthus The vision equalled 1 There was a rather doubtful history of an injury arising from a crashing blow over the nose and eyebrows in 1882. Of this injury slight scars remained In 1886 the right cornea sloughed from the excessive pressure of the increasing tumour, also fistulous openings appeared in the lids The right eye was accordingly excised, and the patient fearing injury to the left eye from increase of the tumour in that orbit desired operative relief The removal was tedious, taking two and a half hours Two hard exostoses were excised from the left orbit by drilling into their bases and cutting between the drill holes With regard to the left eye, vision improved in 12 days from $\frac{10}{40}$ to 1 In 1892 the patient was again seen, there was a small sinus over the left inner canthus, the right orbit was completely filled by a bony growth, part of which in the nasal region was bare, and the lids were exceedingly œdematous and purulent. In 1895 matters were so bad that removal of the growth was imperative With the aid of Mr F O Larkin huge pieces of ivory exostoses were removed (these were exhibited), one mass was evidently an enlarged middle turbinated bone measuring 2¾ × 1½ × ¾ inches A large cavity of the nasal region resulted, through which the right palate could be seen, a couple of years later several plastic operations were performed with the result that the patient could once more pursue his business successfully The patient, who was shown, was now aged 42 years, had V $\frac{20}{20}$, and had no further trouble

Major M T **YARR**, R A.M C, read notes on two cases of

Indirect Gunshot Injuries of the Eye

Both cases occurred in soldiers engaged in South Africa In the first case the man was shot at close range with a Mauser through the head, the entrance and exit wounds were clearly marked on the lower lateral walls of the orbit, mobility of the eyes was not impaired and the globes appeared to be normal The right fundus was normal, the left disc and lower quadrant were "woolly" and raised 3 D, the vessels were tortuous, there were two large hæmorrhages near the disc The right eye had previously been amblyopic, he shot with his left eye, in a month's observation after his recovery from the shock vision improved from $\frac{6}{24}$ to $\frac{6}{18}$, vision in the left eye was *nil* The second case was that of a man who was injured by a Lee Metford bullet during an amateur firework display, he was struck on the left eyebrow Three weeks later ptosis and blindness of the left eye were reported The vision of the right eye now equalled $\frac{6}{6}$ and J 1 and that of the left eye $\frac{6}{36}$ and J 10, there were some abnormal pigmentation of the macula of the left eye and spotty choroidal changes In both cases the globes had not been touched and he believed the cause to be concussion or vibration from a distance

Mr N **BISHOP HARMAN** (London) said he had seen similar cases, one of a medical man whom he saw at the front beside whose head a shell had passed with great velocity, producing a superficial scarring as from a smart burn, there was also complete loss of vision from optic atrophy, probably this might be considered to be a reflex action from the damaged and irritated fifth nerve The second case was that of a field signaller now attending the out-patient department of Middlesex Hospital, he had been knocked over by the explosion of a shell a couple of yards from him. The vision of the right eye had steadily gone down to a very limited perception of light, all the retina was finely detached except at one small part which could be mapped out by the perimeter At the same time the left eye had vision of $\frac{6}{9}$ or with $-0\ 75$ D = $\frac{6}{6}$, the man was confident that this eye was perfect before the explosion as his signalling would show The question might be asked, Had the shock set up a low form of inflammation in the globe allowing stretching of the coats producing detachment of the retina in the one eye and a low degree of myopia in the other?

Mr **CHARLES G LEE** (Liverpool) narrated two cases of similar injuries A man, aged 19 years, was struck with a bullet from an air gun on the outer surface of the left lower lid, it did not penetrate but caused contusion There was free hæmorrhage into the eyeball which later was absorbed, leaving a condition resembling "retinitis proliferans" following the course of the temporal branches of the retinal vessels. There was perception of light only, the globe was shrinking In the second case a bullet from a toy pistol penetrated into the upper and inner part of the orbit, where it was located by x rays On the fundus of the eye was a patch of blood which was now white and degenerate.

---

[1] Ophthalmological Review December 1887

Major YARR, in reply said that he did not think Mr Harman's cases quite paralleled his, he felt they were more like the results following lightning stroke, cases of which he had described, the second case of Mr Lee he thought of particular interest

Dr J A. MENZIES (Rochdale) read a paper on

Detachment of Corneal Epithelium.

The condition he described as essentially one of defective attachment of the surface epithelium to Bowman's membrane, usually following superficial abrasion. Arlt noted cases in 1869 Grandclément in 1888 as traumatic keratalgia, and several other observers at later dates. In his own cases he had noted the onset of the lesion after injury the great suffering caused by it, especially on opening the lids of a morning rubbing the eye in certain ways, and the definite appearance of a ruffling of the epithelium so that even a fold could be seized by forceps or the formation of a blister He believed the acute pain to arise from the interlocking of the ruffled corneal epithelium and the inequalities of the tarsal covering and the frequent relapses to the indifferent fixation of the new epithelium to Bowman's membrane. In his hand thorough scraping had been of most avail, bandaging was useless cocaine drops might be used at night if necessary

Mr C. DEVEREUX MARSHALL (London) objected to the use of cocaine in such cases its action would be sure to clear off the remainder of the epithelium, for it so acted on a normal cornea.

Mr SIMEON SNELL (Sheffield) thought the objection to cocaine was just. He advocated strongly peritomy—he had used it frequently with good results in any case he did not think it good to remove the rest of a damaged epithelial covering

Mr HOLMES SPICER felt that any treatment was rather despairing in America it was counted malarial though he did not believe this possible of home cases he had used quinine and arsenic without good He agreed that the pain was caused by the adhesion of corneal epithelium to the lid. He was inclined to think the lesion herpetic from its occasional alternating character and association in cases with menstruation. In one case he had performed iridectomy where tension had been raised and the cure was complete.

Mr DOYNE thought well of peritomy the 20 minutes relief from the instillation of cocaine was dearly bought with a worse succeeding condition. He was of opinion that the seat of the trouble lay in a diseased endothelial lining to the anterior chamber allowing transudation. He had performed iridectomy twice with good results for this lesion

Dr MCGILLIVRAY said he was sorry that cocaine was so badly attacked, truly it caused evaporation and damage in aqueous solutions but in oil it was not harmful but valuable.

Mr BISHOP HARMAN said he had noted similar bullæ of the cornea affecting captive fish here he had definitely ascertained that the condition was due to fluid infiltrating the layers of the substantia propria which by its deficient development in certain fish tended to break down under unnatural conditions.

Mr LEE read a paper on

Four Cases of Monocular Optic Neuritis

In all cases there was a comparatively sudden onset slight neuralgic pain locally rapid diminution of vision with contraction of field of vision and the appearance of marked choked disc, all these changes being confined to one eye only In none had there been any precedent febrile or grave constitutional disorder nor had there been exposure to the influence of noxious drugs, vapours &c. further there was nothing to indicate injury to the nerve behind the globe nor any suggestion of cerebral mischief In each case recovery was almost or quite complete. He was inclined to think the condition was a local affection and not one indicative o general nerve disease.

Dr GRIFFITH asked how these cases differed from retro-bulbar neuritis all the symptoms, he thought, pointed to this

Mr DOYNE thought the cases resembled retro-bulbar neuritis, in similar cases he had noted a large central scotoma or more correctly a better perception of light at the periphery than at the centre of the field.

Mr SIMEON SNELL (Sheffield) described a

Method of Suturing the Tendons to Form a Better Stump after Enucleation of the Eyeball.

He recalled Bowman's procedure of suturing the conjunctival opening one rarely used now indeed almost forgotten. He aimed at perfect clearness in removing the ball the least degree of disturbance to the embedding tissues and the arrangement of the cut muscles so that they would retract as little as need be and escape union with the scar He attached each tendon by a thread to the adjacent cut conjunctiva before detaching the tendon from the eyeball after removal of the globe the opposing tendons were tied together by these sutures and at the same time the wound of the conjunctiva was closed. Healing was more rapid the stump was more mobile and the glass eye could be used at an earlier date. He had employed the method in 50 cases and considered it a distinct improvement.

A paper on a like operation was read for Mr ERNEST CLARKE (London) He advocated fixing the external and internal recti only to the upper and lower margins of the conjunctival wound, which was further loosely closed by sutures He said that the power of lateral deviation should alone be aimed at in a good stump. Elevation was immaterial.

Mr EDWARD ROBERTS (Manchester) said that he had tried suturing opposing tendons and had given it up as appearing to afford no advantage.

Dr KARL GROSSMANN thought the procedure should be more generally useful than the use of the glass stuffing ball. The latter he had noticed tended to escape from its coverings after three or four years.

Dr F W EDRIDGE GREEN (London) proposed a motion to be recommended to the Council of the Association —

> That in the opinion of this section the employment of the Holmgren test for colour blindness by the Board of Trade is most unsatisfactory as the inefficient character of the test is now well known

He said that the test was fallacious since it depended rather on shade perception than on that of colour by its use notoriously colour blind people had succeeded in passing as sound whilst in the first year of its use by the Board of Trade of the rejected men who appealed there were found 38 per cent. of normal colour perception and similarly in the second year 42 per cent. of normals, thus it tended to pass bad cases and to reject sound men.

The motion was seconded by Dr GROSSMANN who pointed out that cases of scotomata were not distinguished as colour defective by the test these cases were important.

Mr SNELL thought the motion too extensive, especially in the absence of any suggested alternative test.

Mr DOYNE concurred with Mr Snell and suggested that the matter should be deferred

Dr EDRIDGE GREEN said he felt sure that such a motion would help the Board of Trade who recognised the fallaciousness of the test He would be happy to have an inquiry but thought he should ask for the sense of the meeting on the motion.

The CHAIRMAN then put the motion and declared it lost, stating that of 24 then present only seven voted—three for the motion and four against

---

DISEASES OF CHILDREN

THURSDAY JULY 31ST

Mr HAROLD J STILES (Edinburgh) opened a discussion on

The Surgery of the Affections of the Central Nervous System which occur more especially in Children

Mr Stiles submitted a *résumé* and critical review of the several surgical procedures which in recent years have been practised in the treatment of various congenital and other abnormal conditions of the brain and spinal cord and their anatomical coverings. He discussed the surgical measures indicated in the different varieties of spina bifida and in the various forms of meningocele and encephalocele Dealing with congenital internal hydrocephalus he described the methods attempted for the relief of this condition but could not say that they had been attended with much success The surgical treatment of microcephalus had also proved a disappointment though benefit might result when there were signs of local irritation of the brain In tuberculous meningitis Mr Stiles was opposed to operation when the diagnosis was a matter of certainty, but in cases where a doubt existed an operation was justifiable in view of the possibility of the discovery of some condition capable of surgical relief In posterior basic meningitis it had to be remembered that many cases recovered under medical treatment. Surgical measures, such as lumbar puncture, puncture of the lateral ventricle, and drainage of the fourth ventricle were, however, of distinct value in some cases Paraplegia, the result of Pott's disease of the spine, was another condition often susceptible of treatment by surgical measures, more particularly when it was due to an abscess bursting into the spinal canal, when laminectomy was indicated. In the more chronic forms laminectomy should not be practised until rest and extension had been fairly tried Speaking of the surgical treatment of epilepsy Mr Stiles emphasised the importance of removing the dura mater as well as the bone in trephining the skull. This secured a permanent gap in the osseous wall which by a safety valve action accommodated itself to varying degrees of intracranial pressure.

Mr W THELWALL THOMAS (Liverpool) agreed that little could be hoped for in the surgical treatment of congenital hydrocephalus The pathological conditions on which this condition depended were so complicated that no single operation could be advised as suitable to every case, and it was only fair to state in advance that the chance of success was not great On the other hand, acquired hydrocephalus in adults had a much more hopeful outlook. The surgical treatment of spina bifida was analagous to the treatment of a hernia and was influenced by similar considerations One practical point was the necessity of using great care in dealing with the spinal cord, even the slightest injury was apt to cause a permanent paralysis Many cases of spina bifida which appeared very threatening were much improved by the systematic application of collodion, and indeed in this way the necessity for operation could sometimes be avoided.

Mr R. C DUN (Liverpool) deprecated undue haste in the operative treatment of spina bifida unless the sac threatened to burst as many cases subsided spontaneously He preferred excision to the injection of Morton's fluid. Whilst he could not claim a successful operation in tuberculous meningitis he had had success in non tuberculous cases In operating he advised approach through the lateral aspect of the skull rather than by the occipital route In dealing with congenital hydrocephalus the difficulty was to maintain drainage of the ventricles Dr Dun showed a tube made of knitted catgut which he hoped might be useful in this direction

Mr DOUGLAS DREW (London) also discussed various methods of draining the arachnoid space and agreed with Mr Stiles's suggestion to lead strands of catgut into the peritoneal cavity

Mr NOBLE SMITH (London) described the use of a splint in the treatment of angular curvature of the spine He argued that rest alone could not secure fixation Laminectomy might occasionally be required, but under the use of suitable apparatus many cases even though complicated by paraplegia, made a perfect recovery

Professor J CHIENE (Edinburgh) emphasised the importance of rest in the recumbent posture in the acute stage of Pott's disease No apparatus could be an efficient substitute for this Rest and appropriate methods of extension were essential. In the chronic stage the jacket, jury mast, and shoulder collar had their appropriate areas of application In spina bifida he was in favour generally of excision

Mr JOSEPH COLLIER (Manchester) discussed the methods of removing a collection of pus from the spinal canal and advised against the selection of the laminectomy wound as a suitable route

Mr STILES, in reply referred particularly to the proposal to use apparatus in the acute stage of caries of the spine He agreed provided it was understood that the apparatus was combined with, and not substituted for, rest and the recumbent posture

Dr J THOMSON (Edinburgh) read a paper on

Defective Coördination as a Probable Factor in the Causation of Certain Congenital Malformations

He instanced congenital hypertrophy of the bladder, of the colon and of the pylorus and stomach wall when each of these occurred apart from stricture or other organic explanation. In the absence of structural explanation of the hypertrophy it might be conjectured that these conditions were the result of functional disturbances which might well be of the nature of imperfect coördination Such imperfect coördination would be the more likely to occur when the physiological action of the several parts had not advanced to a stage of stable equilibrium.

Dr JULES COMBY (Paris) thought Dr Thomson's explanation a very ingenious one, though he could not admit that it was applicable to all cases

Mr STILES referred to successful treatment of congenital hypertrophy of the pylorus as advocated by Nicholl of Glasgow and described a case from his own practice.

Mr ROBERT JONES (Liverpool) read a paper on

The Surgical Treatment of Spastic Paraplegia,

and quoted a large number of cases in which he had secured added comfort and increased power of locomotion for his patients He insisted on the necessity of prolonged post-operative supervision and education if good permanent results were to be obtained

Mr NOBLE SMITH deplored the neglect by physicians of the chances offered by operation in many of the palsies of infancy in childhood. Even if complete cure could not be obtained considerable improvement was often possible

Dr C O HAWTHORNE (London) readily admitted the significance of Mr Jones's results He could not, however allow that all cases of spastic paraplegia were suitable for operation.

Mr JORDAN LLOYD (Birmingham) could not say that he had been impressed with the permanent value of the surgical treatment of spastic paraplegia

Mr JONES replied and also read a Note on a New Operation for Flail Paralytic Elbow

Mr JOSEPH COLLIER described the after treatment of erasion of the knee joint and urged the importance of preventing fixation of the patella so as to obtain the action of the quadriceps muscle

The question was discussed by Mr STILES and Mr JORDAN LLOYD

Included in the business of the section was a visit to the Embden street School for mentally deficient children, and members had the opportunity of seeing the special methods of instruction there adopted Subsequently an address was delivered by Dr A. EICHHOLZ, His Majesty's Inspector of Schools for the Feeble-minded. Dr Eichholz after defining the type of children suitable for admission to such schools, insisted on the importance of developing their instruction along lines which would fit them for manual occupations, as neither intellectual attainments nor skilled employment could be open to them. To secure permanent success it was also essential to provide supervision and discipline when the limit of school age had been passed. In Birmingham a special After-care Committee had been formed for this object and the example should be copied in every area containing a school of this order The State might do much in this direction, even to the extent of establishing special colonies for the feeble minded, but much must be left to voluntary organisations

Dr G E SHUTTLEWORTH (Richmond hill) urged the importance of excluding imbecile children from these schools He also suggested that the teachers should receive a special training for their work and should be allowed considerable latitude in the methods of education He commended the establishment of permanent organisations for dealing with the adult feeble minded and hoped that something in this direction would be instituted by the Metropolitan Asylums Board.

LARYNGOLOGY

WEDNESDAY, JULY 30TH.

The proceedings opened with a long and important discussion upon

The Diagnosis and Treatment of Foreign Bodies in the Upper Air Passages and Gullet

It was opened by Professor G KILLIAN of Freiburg and a report of the opener's remarks and the discussion will appear next week. After this

Dr ADOLF ONODI (Professor of Rhino laryngology in the University of Budapest) gave a demonstration of

The Connexion of the Isolated Respiratory Fibres of the Recurrent with the Sympathetic and Cardiac Nerves

Dr Onodi said that the connexions of the laryngeal nerves with the sympathetic and the cardiac nerves had been known for a long time but recent observations and his own investigations had shown an extraordinarily intimate connexion which doubtless must have special significance. The connexion of the superior laryngeal nerve with the upper cervical ganglion of the sympathetic and with the rami cardiaci superiores which arose from the latter was known as was also the connexion of the superior laryngeal nerve with the lower cervical ganglion of the sympathetic, the connexion of the external branch of the superior laryngeal being much closer with the upper cervical ganglion of the sympathetic and the superior cardiac nerve. The external branch of the upper cervical nerve sent off a direct cardiac branch or connexions to the upper cervical ganglion of the sympathetic and to the upper cardiac nerve. These anatomical conditions formed in man an exact analogue to the depressor nerve found in animals. In regard to the inferior laryngeal they knew its connexions with the upper cervical ganglion of the sympathetic and with the superior cardiac nerve. *Of great significance* was the observation of Lenhossék according to which the inferior laryngeal nerve arose from a ganglion whilst the ganglion stood in connexion with the pneumogastric by means of a thin root. The lower laryngeal was connected with the lower cervical ganglion of the sympathetic and further with the cardiac branches which took their origin from the middle and lower cervical sympathetic. He had succeeded in demonstrating in the horse the anatomical proof that according to the double function of respiration and phonation of the larynx the respiratory and phonatory nerve bundles ran separately in the trunk of the inferior laryngeal nerve and in the trunk of the pneumogastric. He had demonstrated this for a length of 88 centimetres. Whilst the phonatory nerve bundle could easily be isolated and showed only one connexion each with the ansa Vieussenii and with the cardiac branch it was difficult to isolate the respiratory nerve bundle, for it was very intimately connected by means of eight branches with the sympathetic and the cardiac branches. The photograph showed this remarkably intimate connexion. It was known that in the trunks of the sympathetic, besides the vasomotor and trophic, there were cerebro-spinal sensitive and motor fibres. His investigations had shown that the cerebro-spinal nerve fibres of the rami communicantes ran in the trunk of the sympathetic according to a well-defined system. In the upper part of the thorax and in the neck the larger part of the cerebro spinal fibres of the sympathetic ran upwards and only a smaller part downwards, whilst in the rest of the thorax and in the abdomen just the reverse was the case. The sympathetic constituted the morphological basis in the known connexions for the course of the fibres and their intercommunication, as they were of different origin and different destination. Physiology had until now shown the presence of the depressor fibre and the cardiac branches originating from the superior laryngeal nerve, and his experiments had shown that in the dog the irritation of the sympathetic trunk between the lower cervical and first thoracic ganglion as also of the communicating branches of the brachial plexus would produce a contraction of the vocal cords of the same side. Beyond these observations the morphological facts mentioned had received no pathological or physiological explanation. In particular he drew attention to the intimate connexion which existed between the isolated respiratory nerve-fibres of the lower laryngeal nerve and the sympathetic and the cardiac branches. The morphological foundation was laid in the above-mentioned fact showing an exchange of nerve-fibres of different origin and destination, but the isolation of these fibres and the investigation of their destinations formed still a subject for future inquiry.

Dr J. DUNDAS GRANT (London) read a paper on

A Simplified Operation for Deflection of the Cartilaginous Septum.

This consisted in the first instance in straightening the cartilage by transfixion by means of a strong needle introduced from the concave side in front of the concavity, pushed through to the other side and then back through to the concave side behind the deflection. Two cuts were then made by means of Moure's or Asch's shears through the cartilage, one above and in front of the deflection parallel to the nasal ridge, the other horizontally below parallel to the floor of the nose but not meeting. The cartilage was then manipulated so as to bring about over-riding of the segments at the lines of incision. The operation could be done under cocaine and nitrous oxide gas and the needle was kept *in situ* for a week, no plugging being required.

Dr N. C. HARING (Manchester) read a paper on

Chronic Laryngitis: Correlation of Diagnosis and Treatment.

In this communication stress was laid on the various subdivisions of the disease and their diagnostic distinctions. The author pointed out that in order to secure the best treatment for each case a more particularised diagnosis than that of chronic laryngitis was required. The cases he said fell into groups fairly well defined according to the extent and degree of the congestion which might vary from intense diffuse redness of the whole organ to localised injection and according to the position and extent of the hyperplasia; the condition might be latent, yielding no symptoms and only attracting the patient's attention during periods of exacerbation. It was essential to be able to exclude tuberculosis, syphilis, and early malignant disease in a diagnosis of chronic laryngitis. Speaking of tuberculosis of the larynx, he said that a considerable zone of engorgement might extend around a tuberculous ulcer and an error in diagnosis was easily possible when the ulcer occupied a position where it might escape observation. Except trifling surface abrasions it was extremely doubtful whether ulceration ever occurred in simple chronic laryngitis. During the course of pulmonary phthisis the irritant products of expectoration often set up a laryngeal catarrh which had no other connexion with the tuberculous lesion. Cases of chronic laryngitis he divided roughly into three classes: (1) systemic; (2) due to, or associated with, nasal disease; and (3) independent of nasal disease. In Group 1 local treatment was of little use; the appropriate treatment must be directed to the systemic lesion. In Group 2 the majority of cases of chronic laryngeal catarrh were found to be associated with nasal lesions. It was useless to attempt to cure the laryngitis without relieving the nasal condition and in many cases the relief of the nasal lesion would be almost sufficient as the larynx when relieved from irritation tended to recover. Nasal affections appeared to influence the larynx in three ways: (1) extension of catarrh by continuity of surface; (2) irritation by discharges; and (3) mouth breathing caused by nasal obstruction. The presence of pharyngitis sicca pointed strongly to the root of the disease being in the nasal area. Passing to a consideration of the affected organ itself Dr Haring said that he had found the following classification of much clinical use: laryngitis chronica superior, affecting principally the loose glandular tissues above the cords; laryngitis chronica media, affecting principally the cords; and laryngitis chronica inferior, affecting principally the region below the glottis. In the treatment of the first variety he had found astringent applications of little value; on the other hand the galvano-cautery applied carefully to the hypertrophied tissue had afforded him satisfactory results. The formation of fissures in the inter-arytenoid space was referred to as a troublesome form of this subdivision. Under laryngitis chronica media reference was made to cases which presented cords with grey lustreless roughened surface and which resembled pachydermia laryngis but were distinguished from it by the absence of the pathognomonic tumours over the vocal processes. The several forms of treatment commonly in use were referred to. Under laryngitis chronica inferior it was mentioned that in most cases of chronic laryngitis the portion below the glottis suffered and that it was owing to the neglect of this region that local remedies often failed to effect a cure.

Dr W. JOBSON HORNE (London) agreed that the term "chronic laryngitis" had come to be too loosely used, that it was far too comprehensive, and that a more particularised diagnosis was required to secure the best treatment. At the same time he could not accept the classification of chronic laryngitis as suggested by Dr Haring into "superior," "media," and "inferior." A regional subdivision might be at times clinically useful for purposes of description, but it was not [illegible] on pathological grounds, and after all an appreciation of the pathology of the various forms of chronic laryngitis was the only sure way of reaching the appropriate treatment. He therefore advocated a classification which specified the causes and was based upon pathology.

Dr HARING replied that the subdivisions which he had mentioned were intended to be clinical aids to carrying on the treatment of parts most affected in particular cases.

ETHICS

Wednesday, July 30th

The **President** (Dr S **Woodcock** of Manchester), being detained by a meeting of the General Council, could not deliver an inaugural address and the sitting was opened by Mr J S **Whitaker** (Great Yarmouth), who is one of the honorary secretaries

Pending the arrival of members who were announced to read papers Dr A. H **Bampton** (Ilkley) made a communication concerning

Contract Work in Hydropathic Establishments

In many cases the medical attendant was employed as a sort of "decoy duck" for mere hotel companies The payment he received sometimes did not amount to more than half a guinea per week per patient, and considering the class of patients who frequented such establishments this certainly was not enough Then there was a great deal of advertising in connexion with these 'hydros" which was objectionable from the professional point of view

One member present said that he knew of a case where the medical attendant s photograph was hung up in all the bedrooms After this interlude and more members having put in an appearance, the real business of the morning began

Mr B W **Housman** (Stockport) read a paper on behalf of the Stockport Medical Society He explained that there had been at Stockport some 40 clubs or medical aid societies which in 1895 only paid their medical officers 2*s* 6*d* per member The male membership then numbered about 4000 The profession determined to take action, and with the exception of two practitioners all gave in their resignations, saying that they would not accept any contract work at less than 4*s* 4*d* per annum and this only if a wage limit was established. The members of the clubs were disposed to increase the subscription but they strongly objected to the wage limit. The ultimate result was that the six clubs held by the two medical men who had not resigned increased their subscriptions to 4*s* 4*d* per head per annum and excluded accidents The remaining 34 clubs agreed to do without any medical officers Consequently the club patients had now become private patients, to the great advantage of the medical practitioners. This had also proved an advantage to the clubs, for as the members had now to pay for medical advice there were fewer trivial cases and fewer members drew sick allowances The Stockport Medical Society also succeeded in getting hold of the local Provident Society, where the members paid 1*d* per week and had only one medical attendant The Stockport Medical Society when it took over the management gave the members the choice of 14 medical practitioners, but they soon found that there were many abuses and that a large number of the patients could well afford to pay the usual fees Consequently they wrote a report on the subject and resigned, with the result that the dispensary had now ceased to exist. The speaker then went on to denounce contract work which he maintained was but "a gamble on both sides" He had kept a careful account and had found that within a radius of one and a half miles it cost him in cash 1*s* 2*d* to visit a patient, whether club or private patient so that his club practice had severely handicapped his private practice. At the dispensary they had made up 12 stock medicines of good quality and similar to those which were given to out-door patients at the hospitals Nine out of the 12 cost more than 1*d* per six-ounce bottle, without counting the glass After saying a few words on the degrading effects of contract work Mr Housman proposed, on behalf of the Stockport Medical Society, the following motion —

> That club and friendly society contract work is undesirable and derogatory to the best interests both of patients and of the profession and that the only satisfactory alternative is to adopt a system of payment by tariff for services actually rendered

Dr **William Muir Smith** (Eastbourne) then gave an exposition of the action and position of the Eastbourne Provident Medical Association He described the growth of the movement at Eastbourne and many of the details which he gave are already familiar to our readers He remarked that their difficulty had been with the medical aid societies and not with the friendly societies, thus showing that at Eastbourne only one side of the question had been dealt with. He was able to point out that in substituting a provident society organised by the medical profession itself for speculative and commercial medical aid societies managed by laymen the result had in no wise affected public health On the contrary, the death- and sick-rates had steadily declined. They had the lowest death rate in England and they had also increased the number of persons vaccinated They had more than 4000 members and had last year distributed *pro rata* for the work done more than £1000 among the members of the profession who did this work. In conclusion, he related that a similar organisation, acting under their advice, had been started in New South Wales and was prospering

Dr **Alfred Cox** (Gateshead) then read a paper in which he insisted on the necessity of possessing precise data. Any number of complaints were made on all sides, but to prove that they were justifiable precise figures were needed It was only necessary to take the medical journals of the last six years and by the entries in the indexes it would be seen how much the subject had grown Nevertheless, all this mass of literature gave but few figures Some such figures were to be found in The Lancet reprint of the series of articles on the Battle of the Clubs and correspondence to the *British Medical Journal* had given a few more figures, but these were not enough He had therefore made calculations in regard to his own practice for a period of three and a half years. With the Shepherds Society the average payment for that time had been 1*s* 1¼*d* per visit, with the Druids 1*s* 6½*d*, and the average of all his clubs equalled 1*s* 4½*d* On the other hand, he had found that it cost him 1*s* on an average for each visit and in this he had made no allowance for clothes, pleasure, or skill The shilling represented the indispensable out-of pocket expenses A the club patient provided his own bottle for medicine, an allowing 1*d* for errors, he found that the club patient yielde a net profit of 3½*d* per visit and the private patient 1*s* 6 per visit, and the point was that both belonged to muc about the same class of workmen and both were equally we able to pay the full fees

Dr W **Richardson Rice** of the Coventry Public Medic Service, read a paper giving a short history of what ha occurred in that town, facts with which our readers are al familiar He urged that there was a class for which contra work was necessary and that the British Medical Associatio might with advantage lay down rules as to how this coul best be provided by the medical men themselves without an intermediaries Much depended on securing the services a good collector who had tact and who would refrain fro canvassing But even if there was a little canvassing it wa on behalf of all the medical practitioners and not to th special advantage of any one individual It was only quarter day that the members of the Public Medic Service could change their medical adviser and as the were secured for three months this enabled the sale a practice for it served as a good introduction. At Coventr they paid their dispensing chemist 1*s* per head per membe but a large London firm had offered to open two establis ments at Coventry with qualified assistants and to take les No practitioner was allowed to have more than 2000 members on his books and they had, of course, established wage limit.

The **President**, who had by this time arrived and take the chair, said that now all the papers bearing on the subjec of contract work had been read he would throw open th discussion, taking for its basis the resolution proposed b Mr Housman, and which, it should be mentioned, had bee formally seconded by Dr J **Dalberg** (Manchester)

Mr **Whitaker** supported the motion which he defined a striking at all contract work including that which ha been organised by the medical men themselves at Eastbourne and Coventry Even if the medical practitioner wa sufficiently paid contract work engendered suspicion o both sides The patient thought to obtain more than wa his due and at the same time suspected the medical man o neglecting his work. Then if a friendly society offered large sum their medical officer was placed in the ignominiou position of having to pay court to the more influentia members of the managing committee Yet something had t be done for those who could only afford to pay by weekl instalments The medical profession, as a whole, shoul take the matter in hand. The friendly societies ha elaborate statistics It was easy to ascertain what wa the sick rate and then to estimate how much insuranc money ought to be paid to provide the means of giving fees to the medical practitioners for work actually done. As a step in that direction the medical men migh themselves seek to organise the contract work, as had been done at Eastbourne and at Coventry, but the ultimat object should be the total abolition of contract work and th substitution in its stead of a system of insurance for the payment of fees.

Mr GEORGE JACKSON (Plymouth) supported the principle of small weekly payments. Otherwise a large class of patients would resort to the Poor law medical officers. He, however objected to the Eastbourne Medical Provident Association doing other men's work by vaccinating gratuitously

Mr R. H. WOLSTENHOLME (Manchester) said that he would support the first part of the motion only Contract work led to hospital abuse, but there were many other alternatives. In response to Dr Alfred Cox's request for figures he submitted the following in regard to a society with which he was acquainted —Visits in the course of one year 8272 consultations, 13 673 , medicines dispensed, 16,106 , candidates examined, 257 and births attended, 44 Total payment received for all this work, £314 18*s* He did not think that medical men should go about establishing cheap dispensaries for the people How could they protest against contract work when they were living by it? The Eastbourne method worked out, he was told, at 6*d* a visit and 6*d* the medicine. They had ' sixpenny doctors in Manchester and he did not like them but, as they charged 1*s* a bottle for medicine they got 1*s* 6*d* and this was better than the Eastbourne average. There were, he noticed at Eastbourne and elsewhere enticing lists of high fees for surgical operations, but this was only a snare and delusion for in such cases the patients all went to the hospital.

Mr E. H. T NASH (Accrington) qualified club practice as immoral because it led to the neglect of surgical and important cases which the club medical officer passed on to the hospital. In the North the collecting system prevailed. Patients paid full fees at the rate of 2*s* a fortnight till the bill was settled

Dr S. CRAWSHAW (Ashton under Lyne) did not believe that private patients would pay if they resorted to the collecting system. They would continue to consult their medical attendant till he pressed them too severely and then they would go to someone else There would be many bad debts. The contract work was the best that could be done with this class of people.

The PRESIDENT now thought the time had come to close the discussion To sum up he agreed with Mr Wolstenholme, for he found that at Oldham there were no clubs or contract work. The practitioners there had agreed among themselves not to accept any contract work whatsoever The workmen paid sometimes as much as 2*s* 6*d* a week till they had settled their bill. It was necessary to employ a collector to get the bill paid by instalments, but this was more dignified *and advantageous than the contract system.*

Dr MUIR SMITH explained that at Eastbourne they had undertaken vaccination before the adoption of the amended Act and had no desire to continue it. Their movement had not a mercenary object , its purpose had been to free the medical men who used to be bound hand and foot by the medical aid societies.

Mr HOUSMAN, in reply said that he was glad to see that they were unanimous in their dislike of contract work. They would not now discuss whether this contract work should be organised by medical men and he was pleased to hear that in the North they had been able to dispense with it. He would accept the amendment arising out of Mr Wolstenholme's objection to the latter part of the motion The motion would therefore, read as follows —

> That club and friendly society contract work is undesirable in the best interests of both patients and the profession.

On being put to the meeting in this form the motion was carried with but one dissentient vote given by Dr W Muir Smith of Eastbourne. There were then 33 members present and several among them did not vote at all.

NAVY ARMY AND AMBULANCE.

WEDNESDAY JULY 30TH

The PRESIDENT Brigade-Surgeon Lieutenant-Colonel G S ELLISTON V D (Ipswich) in his opening address, said that the new army medical warrant would doubtless occupy *a considerable portion of their time for discussion* The new warrant appeared to be a good one as far as it went. The Secretary of State for War practically adopted all the suggestions made to him by the journal and sub-committee of the Association, and, if administered in a fair spirit, a good class of young medical men would doubtless enter the service. In its report the sub-committee expressed much satisfaction in the enhanced status of the Director-General in rank, position and emolument. As a member of the War Office Council and Army Board he would now be able to exercise an important and beneficial influence, not only on the efficiency of his own department, but of that of the army at large in all that related to its sanitation." During the war in South Africa the Army Medical Department had come in for more than its share of criticism and in the near future it might be the turn of the Navy Medical Service to go through the same ordeal therefore it behoved them to be up and doing so as to be prepared for any eventuality Mr Arnold Forster in his speech introducing the Navy estimates, said that the Royal Navy now had a hospital ship in the Mediterranean, and that steps were being taken to provide material for three other hospital ships in the event of war The hospital ship now in the Mediterranean was the *Maine* which had been in commission for nearly a year her duty was to collect the sick from the squadrons and to convey them to the Royal Naval Hospital at Malta, and if a large *number of invalids had to be sent to England she* brought them home. The ship had proved an enormous boon to the sick, who were now treated afloat and were moved about with the greatest comfort and convenience. The three other ships for which material was to be provided for use in the event of war would carry a staff of naval medical officers and nursing sisters , they would be in attendance upon the fleet during an action and would receive the wounded on board. Mr. Arnold Forster also stated that steps were to be taken to provide the necessary material for a considerable number of additional ships for use as hospitals in case of war Some of the experiences of the Japanese in the war with China showed the need of hospital ships to accompany the fleet into action. Now that the war in South Africa was over they might look back and realise the great work which the Royal Army Medical Corps had accomplished In spite of the hostile criticisms and unfounded charges brought against the corps there was little doubt that the general verdict of the future would be that in no previous war had the sick and wounded been so well looked after as in that one. When the war broke out it was well known that the Royal Army Medical Corps was barely up to the peace footing and it was really marvellous how the late Director-General succeeded in supplying the medical *matériel* and *personnel* with every unit that embarked Of course, this could only be done by the help of the various volunteer organisations the Militia Medical Staff Corps supplied 500 men the volunteers 600 and the St. John Ambulance Brigade furnished 2000 men. The feature of this war had been the way in which the volunteers and the civil and military portions of the medical profession amalgamated and worked together and the new departure of sending out 800 female nurses was attended with the best results. Considering the undermanned state of the Royal Army Medical Corps the War Office was fortunate in having these reserves to draw upon, and yet the chief organisers who bore the heat and burden of the day were allowed to leave the service without any official acknowledgment. Referring to this point the late Sir William Mac Cormac publicly stated that no one who had not been in South Africa itself could know of the difficulties under which the medical department had laboured. They had been blamed for that for which those in other departments were responsible, and it was somewhat strange that the Government had allowed Surgeon General Jameson to leave the army without the customary recognition given to every one of his predecessors and withou one word of thanks or acknowledgment." All through the war a person could hardly read the casualty lists without being struck with the appalling loss of life from enteric fever , the losses in the field were small compared with it and sanitarians could not help thinking that much of it was due to preventable causes. In civil life the municipal authorities held the medical officer responsible and expected him to find out the cause and to suggest measures for stamping out the disea o regardless of the cost In military life this did not appear to be the case a general who had a large portion of his force down with enteric fever through [illegible] *of ordinary* precautions in guarding the purity of the supply and preserving the cleanliness of his camps get censured, but the sanitary officer whose advice taken was pronounced incompetent and indirect blamed. No doubt the sanitary officer in war stantly be advising things distasteful to the this was possibly why the post was abolished at the commencement of the war The combatants, however, should bear in mind that by safeguarding their water supplies attending to the sanitation of camps, and preventing infection of troops on the march, they were not only reducing the amount of sickness but were adding to the efficiency of the field force as a fighting machine The question of sterilising drinking water for active service was no new one, for Herodotus, "the father of history," recorded at the end of his First Book as follows "Now the great king (Cyrus) goes on campagne with provisions carefully prepared at home, and with cattle Moreover, he takes along with him water from the river Choaspes, which flows past Susa, of the water of that river and no other does the king drink This Choaspes water is first boiled off and a marvellous number of four wheeled mule wagons, carrying it in silver vessels follow him from place to place wherever he marches" So that 2500 years ago we find this great Persian monarch carefully attending to the purity of his drinking water, and whatever happened to the rest of his army he took good care not to run any risk himself The new army medical warrant did not refer to the volunteer medical service but the Secretary of State for War had recently granted some important concessions Authority was now given for the formation of brigade bearer companies as independent units, on similar lines suggested in a paper which he (the speaker) read before this section at the meeting of the British Medical Association in 1900 Another concession had been the incorporation of the Volunteer Medical Staff Corps into the Royal Army Medical Corps (Volunteers) with the abolition of the compound title of the officers. They all felt that the Manchester Corps had well earned distinction, that fine corps being upwards of 800 strong and having furnished strong contingents for service in South Africa

A paper contributed by Staff Surgeon W J COLBORNE, R N, on

The Duties of Medical Officers in Connexion with a Naval Action

was read in his absence. He dealt with the subject under three heads (1) preparation in time of peace, (2) conduct during an action and (3) duties after the action Each of these was handled with much technical detail

Fleet Surgeon G KIRKER, R N (Haslar), read a paper on

The Treatment of Wounded in Naval Actions

He said that certain scant information was obtainable from the records of the Chino Japanese and the Hispano American wars, and the missing details could be filled in by persons acquainted with modern guns and battleships, supposing one modern power were pitted against another He had read a paper last year at Cheltenham on the same subject under the three heads—(1) the surgeon's station, (2) the time of treatment, and (3) the conveyance of the wounded He would now reverse that order and deal first with the conveyance of the wounded This matter depended on the means of conveyance—the stretcher—and on the openings and passages available for use. He dealt with the facilities afforded by the "Kirker ambulance sleigh," which was so well received last year at Cheltenham and was then fully dealt with He had made certain alterations in its construction since, it was now collapsible and its transverse diameter could be increased or lessened at will He had provided perineal bands instead of the central saddle seat There was now a lifting sheet to place the patient on the stretcher and to remove him on to the operation table (The working of the stretcher, which attracted the interest and warm praise of the assembled naval and military surgeons was then demonstrated) The "sleigh" had been tried in the Channel Squadron and had been on the whole favourably reported upon and would now probably be adopted by the Admiralty There were two classes of ships—those which possessed, and those which did not possess ammunition hoists, and down these, if present, the wounded men could be lowered during cessation of the passage of ammunition The hoists should open on each deck to allow of the wounded being admitted to the hoist This procedure would be very simple and easy with the "Kirker sleigh." The hoists should in future, with this end in view be constructed in a less constricted manner 2. Time of treatment. The medical officers should not go on deck to treat the wounded, as efficiency was what was most desirable and the medical officers should not be incapacitated just when their services would be most needed. They should remain on their ship, but together with their instruments and appliances should be relegated to a safe place Hospital ships were excellent but could not succour every ship and each fighting ship ought to be able to care for its own wounded until such time as help could be obtained from a hospital ship 3. The surgeon's station At present there was no proper station assigned to the surgeon and it was desirable to have a properly equipped place and as far as possible free from septic and insanitary conditions, as in the Japanese and German navies. This place would be as useful in peace as in war In war the surgeon and his instruments would be adequately protected Poisonous gases were also factors to be taken into account Hospital ships would not always be at hand, especially in running fights and isolated fights with single ships and cruisers Fleet actions might also cover too large an area. He then finally treated in detail the duties of the surgeons and assistants with reference to treatment and transport of wounded in action

The PRESIDENT commended Fleet Surgeon Kirker for his careful and practical paper and thanked him for the evident pains expended in its preparation He pointed out the need for the efficient lighting of the dressing station, as also for the efficient ventilation of the operation rooms. There was no doubt that the "Kirker sleigh" was very well designed and he was surprised that it had not been adopted by the Admiralty before. Other nationalities had stepped in and had demonstrated its utility

Inspector-General A TURNBULL, R.N, retired (London) said that it was very interesting to note that there was a great deal in the old adage of there being "nothing new under the sun." He had lately been looking up some old records and he found some Admiralty regulations dated 1730 and headed "Hospital Ships," and these regulations showed that even then the arrangements were admirable. Hospital ships were things that could be very easily and rapidly equipped and fitted out. Cyrus and his water boiling outfit was another instance of the new in the old

Surgeon General T F O'DWYER, A.M S, said that undoubtedly Surgeon Kirker was the first to draw attention to the matter in such a way as to attract public attention. Immediately afterwards the *Times* publicly discussed the whole matter There were two opinions in the navy—one represented by Surgeon Kirker, who held that such ships should have proper accommodation, and others who said that that was impossible They as a nation seemed to be too conceited to learn from others At Aldershot an American staff officer who had been sent to Europe to learn was not ashamed to learn from us Both the navy and army wanted many more Lord Charles Beresfords Public opinion was the only means by which these reforms could be brought about. The army had benefited by public opinion and the navy would no doubt do so also Nevertheless, the navy was most conservative and did not like to change. Public examination of these most important matters was what was wanted, after first obtaining the opinions of those who built the ship, of those who had to fight her, and then, finally, of the man who had the medical care of her

Surgeon Major G A. HUTTON, retired (Leamington), believed that Sir Frederick Treves had stated that it was better not to attempt to attend to the wounded over and above applying first temporary dressings whilst a battle was proceeding He also believed that the present Director General was sent by the home Government to observe the arrangements in the Chino-Japanese war

Surgeon Major G K. POOLE, I.M.S, retired (London), would have liked the gentlemen contributing papers to have touched upon the matter of necessary procedure in cases of collisions and explosions, which might have been dealt with It was no new thing to have to make shift in the services This discussion should be brought well before the authorities of the navy The mercantile navy should also be efficiently officered from a medical standpoint.

Dr. F W FORBES ROSS (London) said that whether or not they were agreed as to the desirability or otherwise of properly equipping each warship or depended mainly on hospital ships, the fact remained that the "Kirker sleigh" was most useful in either event and especially in cases involving the transport of the wounded by sea, from shore to transport or hospital ship, or from ship to ship

Fleet Surgeon KIRKER, in replying, said that hospital ships were by all means to be provided and that he cordially advocated them and as many as possible should be provided All modern ships were lighted by electric light. All were artificially and naturally ventilated above the armoured deck and mainly by artificial means below the armoured deck.

The PRESIDENT put the following motion to the meeting proposed by Surgeon Major POOLE, and seconded by Surgeon General O'DWYER —

That it be a recommendation to the British Medical Association to suggest to the naval authorities the desirability of improving the accommodation and arrangements for the treatment of the wounded on board ships in action, till they can be transferred to hospital ships or suitable hospitals on shore.

The motion was unanimously endorsed

TROPICAL DISEASES.

WEDNESDAY JULY 30TH.

President's Address

Sir WILLIAM R. KYNSEY C.M.G., the President, after a few preliminary remarks referred to the great work recently done by Laveran and others in malaria He continued In the history of the past year there is no great discovery to be recorded, it may be looked back upon as one of steady progress in elucidating some of the many problems of tropical medicine, the greatest and most beneficent being in the scientific prevention of disease. In the case of yellow fever the mosquito—a culex, not anopheles—has been tried and found guilty of being the sole agent in the spread of that disease. In Havana yellow fever was endemic for a century and a half during the past year it has been freed from the scourge by killing the mosquitoes in the neighbourhood of each focus of disease as discovered, and by carefully disinfecting every house that had lodged a yellow fever patient in order to destroy the mosquitoes that had bitten a sick person. This great sanitary triumph must ever redound to the honour of American medicine. No excuse is necessary in this section for dwelling a little on the important subject of the prophylaxis of malaria. An epidemic of any kind is among the most costly in life and money that can befall a town or district. An epidemic of malaria differs from other outbreaks of disease in this important fact that its effects are not limited to the deaths it causes but that it often leads to years of suffering poverty and depopulation. I have high authority for stating that taking one year with another malaria destroys twice as many people in India as cholera, small pox, and all other epidemic diseases put together It is a matter of history that the same cause almost annihilated the soldiers of the Walcheren expedition and the army under Wellington in Spain was so assailed by malaria that according to Ferguson the enemy and all Europe believed the British forces were exterminated Malaria stopped the great Panama scheme of De Lesseps. I have known districts in Ceylon almost depopulated A most disastrous outbreak occurred some years ago at Galle—a town previously malaria free—attended with great loss of life in consequence of the construction of a railway the embankments of which were made by excavating pits at the sides that soon were filled with rain water In those days the origin of the fever was of course attributed to disturbance of soil. We now know the pits provided breeding places for the anopheles and the Sinhalese and Tamil labourers from malaria districts supplied the organisms. Although we were ignorant of the true conditions which caused the outbreak we advised the filling up of the pits on the disturbance-of soil theory with satisfactory results proving that much can be done in the prevention of disease before full knowledge of causation is reached. I will only occupy a few minutes of your time while I describe two experiments—one made by the Colonial Office on Dr Patrick Manson's advice and the other by the Japanese Government which clearly show it is both possible and practicable to prevent malarial infection In the experiment conducted by Dr Sambon and Dr Low in the Roman Campagna and in London in order to prove the truth or error of the mosquito malarial theory and also how far protection against malaria might be consistent with the ordinary avocations of life two experiments were necessary one that healthy persons in London should be bitten by infected mosquitoes from a malarious region and the second that men should live in an undoubtedly malarious place during the fever season being protected only from the bites of mosquitoes Those bitten in London contracted ague Dr Sambon and Dr Low and two others lived in a mosquito-proof hut in a most intensely malarious place in Italy, where all the inhabitants suffered from malaria. The four inhabitants of the hut remained perfectly healthy all the time and I believe are so still The experiments by the Japanese Government were carried out on the island of Formosa, and they furnish a most conclusive demonstration of the relations between mosquitoes and malaria. A battalion of soldiers who were completely protected from mosquitoes for 161 days during the malaria season escaped the disease entirely whereas there were 259 cases of malaria in another battalion in the same place and during the same length of time not protected from mosquitoes. I am sure you will agree with the conclusions of Dr Sambon and Dr Low that their experiment prove that mosquitoes only are capable of transmitting malarial fever that protection from their bite implies absolute immunity and that protection can be easily obtained. If further proof is considered necessary for large bodies of men it is furnished by the Japanese experiment. By a study of the life-history and surroundings of the anopheles and by varied and long continued experiment Ross has determined the best means of preventing malarial infection. He advised the extermination of the anopheles and although this is difficult it is not so difficult as at first sight it appears These mosquitoes breed in small pools of a certain kind easily recognised and easily dealt with always close to human habitations, as the females must pass frequently between the pools where they lay their eggs and the houses where they obtain their food If the anopheles are found in a house the breeding puddles are close by The great practical points derived from Ross's work are two 1. That the life of the anopheles is in direct and intimate relation with the annual epidemics of malarial fever 2. That it is only necessary to drain the anopheles puddles and not the whole of a malarious district I believe the discovery of the malarial parasite and the investigations into the life history of the mosquito which conveys it to man have placed us in the position to suggest measures which if carried out would have the effect in an unhealthy district of largely reducing the amount of malarial fever and eventually of exterminating it. 1. Malarial fevers should be included and notified among infectious diseases so that precautions could be taken to prevent their spread. 2. Persons, especially children, suffering from malaria infections, primary or recurrent should be isolated and treated with quinine to prevent as far as possible the infection of mosquitoes 3. Persons infected with malaria should be prevented coming to a healthy place to infect mosquitoes 4 The puddles in which the anopheles breed should be drained and filled up or treated with kerosine to destroy the larvæ. 5 Doors and windows of houses gaols and hospitals in malarious districts should be screened with wire gauze and beds should be provided with netting to prevent mosquitoes entering and biting the occupants. I am painfully aware how far this address falls short of what might have been accomplished by a more skilful hand writing upon the all important subject of malarial prevention but my remarks will not be thrown away if they induce those not acquainted with recent work to take an interest in and to appreciate the wonderful results in tropical medicine which have followed on the discovery of the malarial parasite.

> "Let knowledge grow from more to more
> But more of reverence in us dwell;
> That mind and soul according well
> May make one music as before
> But vaster

Prophylaxis and Treatment of Beri beri.

Dr P MANSON C M G (London) opened the discussion by reading a paper devoted to the study of the etiology of beri beri more especially as regards the part played by rice as a medium of infection. An agreement in regard to what the term beri beri indicated was a necessity before entering into a discussion on the subject. They knew that the term had been applied to ankylostomiasis to epidemic dropsy to sleeping sickness and to several specifically distinct forms of neuritis Clinically beri beri was a multiple neuritis but in the tropics as in temperate regions there were many kinds of peripheral neuritis although all had necessarily much in common clinically Arsenical neuritis was uncommon in the tropics but what was generally regarded as beri beri had nothing to do with arsenic. Arsenic might be found and was found in the hair of beri beri patients and even in Chinese tobacco, but there seemed no correspondence between the distribution of beri beri and the general area of the use of arsenic Again so called malarial neuritis was in his opinion in the vast majority of cases really beri beri. Beri beri might co exist with malaria or with tuberculosis yet with either disease the beri beri affection was merely concurrent. Whilst fully recognising its inadequacy Dr Manson suggested the following features as a basis on which to found the recognition of beri beri as a distinct form of multiple peripheral neuritis and as more or less distinguishing it from other pathological groups with neuritis as their leading clinical phenomenon (1) ignorance of its cause, (2) its occurrence as an endemic and epidemic disease, (3) its proneness to produce cardiac disabilities and dropsy, (4) non implication of the cranial nerves with the exception of the pneumogastric, (5) non implication of the intellectual and emotional centres, (6) rarity or complete absence of trophic skin lesions, and (7) high rate of mortality under certain conditions. Assuming, and once more emphasising that he did not lose sight of the fact that it was an assumption, that they were dealing with only one form of neuritis in what they called beri beri, Dr Manson held that this neuritis was produced (*a*) by a toxin, (*b*) the product of a germ operating in (*c*) some culture medium (*d*) located outside the human body Further, he held that (*e*) the said toxin entered the body neither in (*f*) food nor in (*g*) water but was introduced through the skin or was inhaled The immediate cause of beri beri he held to be a toxin. The generally recognised most important measure in the management of a case of beri beri was removal of the patient from the place in which he sickened. This fact seemed to counter indicate the presence of a germ in the human body affected by beri beri. The many germs discovered from time to time in the blood of beri beri patients had been discredited The absence of any germ in beri beri had been again recently refuted by Dr Stanley of Shanghai Although no germ was present in the blood the toxin of beri beri was produced by a living germ The proof of that lay in the fact that the disease could be introduced into virgin country and there spread That was to say, the hypothetical cause was capable of being transmitted and of multiplying Spontaneous multiplication was a property peculiar to living things Therefore the originating agent of the toxin of beri beri was a living thing—a germ. Dr Manson quoted observations made by Dr J Bolton in the island of Diego Garcia and by Mr E. A. O Travers in Kuala Lumpor Both of these, especially Mr Travers's observations, went to prove that the toxin of beri beri did not enter the human body in food That beri beri was not conveyed by water had been proved many times, so that it would appear that neither by food nor by water was beri beri spread. So far unfortunately, they had nothing to show either what the toxin was nor what the germ was that produced it. Neither was the precise nidus in which it was produced known nor the way the specific agent gained access to the body

Captain E R. ROST, I.M S, dealt with the subject of

The Cause of Beri beri

He observed that during an outbreak of beri beri in a gaol in India pigeons that lived under the gaol roof were affected by an epidemic disease which caused paralysis of their wings and death In rice-water liquor and in mouldy rice he found a diplo-bacillus. He also found this organism in the blood and cerebro-spinal fluid of a large number of beri-beri cases The infected blood was removed and cultures were made. The cultures were then injected into pigeons and a disease was induced which caused death and in the blood of the pigeons the same diplo-bacillus was found. An exactly similar disease was produced in fowls (1) by feeding them on fermenting rice, (2) by feeding them on mouldy rice, (3) by intra peritoneal injections of rice water liquor, (4) by subcutaneous or intra peritoneal injection of the venous blood of beri beri patients, and (5) by re injection from fowls suffering from the disease produced as above He then drew attention to the etiology of beri beri in Rangoon, which so remarkably favoured the idea of a rice origin of the disease as to leave in his mind little doubt as to the causation of the disease being due to the medium of rice infection

Dr L W SAMBON (London) failed to see how they could annul the evidence accumulated as to rice being a possible factor in the etiology of beri beri. He did not think that rice was pathogenic because deficient in mineral and nitrogenous matters but that rice might become the vehicle of the disease by being specifically contaminated. He did not agree with beri beri being a toxin produced outside the body He believed that beri beri was caused by a parasitic agent that ved within the human body because the clinical sympto s, &c., suggested a different distribution of the parasite n different patients and in different stages of the disease n the same patient. He suggested that provisionally t ey should (1) restrict the rice diet to grain of good quali , (2) exclude previous sufferers from beri beri from a gang of coolies, and (3) isolate beri-beri patients

Major RO ALD ROSS, C B (Liverpool), had now examined the ha r of 30 persons suffering from beri-beri and arsenic had b en found in 10 cases It was peculiar that the arsenic was found only in recent cases the older cases giving negative results in that respect All this might be merely a curious coincidence On the other hand, it might point to a real co nexion between the poison and the disease from which the patients were suffering, a disease which of itself was very m ch like chronic arsenical poisoning

Dr C W DANI ELS (London) said that tropical peripheral neuritis included o her diseases than beri beri, especially a post-dysenteric peripheral neuritis It was owing to the inclusion of many diseases under the description of beri beri that so many widely different conclusions were arrived at by workers in different countries, as they were not always describing the same disease

Mr JAMES CANT LIE (London) said that they must distinctly keep before them the fact that beri beri was an infectious disease and was not due to mere scanty or deficient food He had seen i n a general ward, in which were cases of beri beri, the disea se spread to patients with open wounds whilst purely medica l cases escaped, although all were supplied with the sam e food All the evidence from Japan and the Dutch Indies seemed to show that the improvement in several well know n instances was due not to the improved food but to improved hygienic conditions. Although discrediting the conveyance of beri beri by food or water it was difficult to understand how persons with merely a toxin in their blood could introduce the disease in virgin countries

Dr W T PROUT (Principal Medical Officer, Sierra Leone) gave details of a ship load of 500 negroes arriving at Sierra Leone from Panama, when it was found that half the negroes were the subject of beri beri. Although the sick were landed and treated o n shore the disease did not spread nor were the attendants upon the sick attacked. He strongly supported Dr Manson's theory of beri beri being due to a toxin produced outside the body

Dr P A. NIGHTIN ALE (Harrogate) said that in Bangkok an epidemic of beri beri occurred some 18 months ago, although fresh rice was always used there. Beri beri was not endemic in Bangkok and how the disease reached the town was unknown.

The PRESIDENT said that beri beri or a form of peripheral neuritis existed in Ceylon in the early years of the occupation of that island by British troops, but as far as he was able to ascertain it was confined to native troops, especially to the Malays, and never spread to the natives of Ceylon. Beri beri had now entirely disappeared from Ceylon and the only cases seen there were landed from ships, but in no instance had he seen the disease spread. He thought that Dr Manson s theory of beri beri might be given in the line of Ovid—

'Non hominis culpa, sed ista loci

Dr NIGHTINGALE read a paper on

The Clim ate and Diseases of Bangkok

The diseases most prevalent in Bangkok were malaria, gastro-intestinal diseases, dysentery and diarrhœa, sprue, hill diarrhœa, typhoid fever, cholera, leprosy, and renal diseases Malignant disease was rare, as were also elephantiasis and beri beri Plague was unknown but climatic buboes (pestis minor) were prevalent.

Major F SMITH, R.A.M C, in dealing with the subject of

Enteric Fever in Sierra Leone,

said that it was very occasionally met with in that country and he recorded but 13 known cases, in some of which the disease arose endemically

---

THE ANNUAL MUSEUM.

(*Continued from page 334*)

II —FOODS AND FOOD-PRODUCTS

The display of special foods was on a decidedly smalle scale than on previous occasions, and the individual exhibit appear to have had less space allotted to them than hitherto

Nor was there any striking novelty in special dietetic preparations. Specially prepared milk, milk products and *malted foods were chiefly in evidence. The products of the* Aylesbury Dairy Co., of 31, St. Petersburgh place, Bayswater London W are well known to be of a standard kind. Besides special milks for special needs the company exhibited specimens of kefir and kefir powders for the preparation of kefir at home where daily delivery is impracticable. By a careful selection of organisms a ferment is obtained which produces pure lactic and alcoholic fermentation Kefir contains less alcohol and carbonic acid but more proteids (partly pre-digested) than koumiss and serves as a mild gastric stimulant. Very general interest was shown in the exhibit of sterilised milk by Messrs. C Dreyer and Co. of Thames-chambers, Beer lane London, E C As we have pointed out, though sterilised this milk is not boiled and no chemical preservatives are employed. One very important advantage of sterilising milk without the aid of heat is that the milk is free from the so-called boiled" flavour The Walker Gordon Laboratory Co of 79 Duke-street, London, W, exhibited specimens of modified milk made up to any prescription required with regard to its composition. On this stall also were specimens of Pasteurised whole milk and paraffined fresh whole milk stated to be unheated and free from preservatives The preparations of the International Plasmon Limited of 56, Duke-street, Grosvenor-square, London, W are deservedly well known by reason of their real dietetic value the foundation of them being plasmon—the proteid of milk so separated as to retain the original organic characteristics of milk albumin Mention should also be made of the plasmon diabetic biscuits which, while containing milk proteid, exhibit a negative reaction as regards both starch and sugar Many varieties of food suitable for the use of diabetic patients and leaving them quite a wide choice in the matter were exhibited by Messrs G Van Abbott and Sons, of Borough London S E Not far off was a stall devoted to the exhibition of 'Universal Digestive Tea by the company bearing that name, of Colonial House Dolphin place Ardwick, Manchester The tea is said to be treated in a special way with oxygen which is said to neutralise the astringent principles. Experiments were quoted recording the comparatively small effect of such tea upon the digestive processes as compared with tea not treated in this way The preparations of the Myosin Albumin Meat Extract Company, of 107 Strand, London W C have been submitted to criticism in THE LANCET laboratory The results showed a remarkable proportion of pure unchanged beef muscle albumin, and therefore the preparation is a real nutrient, while it is easily assimilable. Messrs. Cadbury Brothers of Bournville near Birmingham, exhibited specimens of their cocoa which as is well known undergoes no method of treatment by which foreign substances are introduced Close by were the meat preparations of Messrs. Cosenza and Co of 95 Wigmore-street, Cavendish square London, W These comprised a *consommé* contained in a gelatin capsule and a tonic bouillon containing a notable amount of iron A very good example of milk food was that of Mr Henri Nestlé of 48, Cannon street, London E.C which presents the elements of a complete food for infants. The condensed Swiss milk of this firm is well known for its rich proportion of cream. Messrs Keen Robinson and Co. of Garlick hill. Cannon street London E.C exhibited specimens of Keen's mustard and of the well known patent barley for making barley water and specimens also of patent groats The Strenbo extract of meat, prepared by Strenbo, Limited of Hulme, Manchester is marked from many other similar preparations by containing an important quantity of the really nutritive matters of meat The highly refined vegetable fat known as albene maintains its popularity as a substitute for lard or butter for cooking and baking purposes samples were exhibited by the manufacturers Messrs. Broomfield and Co. of 63, Upper Thames-street London, E.C Quite recently we have referred to maltova, a combination of active malt extract with raw egg. Obviously the preparation is of a highly nutritive kind. Samples were exhibited by the Maltova Food Company 11, New Station street, Leeds A comprehensive series of meat preparations was shown by Liebig's Extract of Meat Company of 9 Fenchurch avenue, London E.C. These included lemco a concentrated extract oxo, a fluid beef containing the nutrient portions of meat and peptarnis, a concentrated peptone of beef Messrs. Callard and Co. of 65 Regent-street, London, W exhibited their well known starchless and sugarless breads, biscuits, and cakes, besides beverages and marmalade free from sugar *Messrs. Carnrick and Co Limited of 24 and 25* Hart-street Bloomsbury London W C report a greatly improved taste in regard to their beef peptonoids. The same firm exhibited a pre-digested preparation known as liquid peptonoids, which is stated to be made from beef milk and gluten. Mr Hans Hoff 29 New Bridge-street, London, E.C. exhibited his old-established proprietary malt extract, and on the same stall ironal was exhibited a preparation of organic iron said to be easily assimilated and without the objectionable effects of ordinary iron salts. Somatose contains the true albumose derived from beef and and is consequently a powerful and easily assimilated food. It is combined also with iron and with a proteid of milk. Pure somatose is mentioned as a useful dusting powder for ulcers by encouraging cicatrisation. The preparation is manufactured by the British Somatose Co., of 165, Queen Victoria street, London E.C. Messrs Fairchild Brothers and Foster of Snow hill buildings London E.C. exhibited their special preparations of enzymes the exhibit including the zymine peptonising tubes and a peptogenic milk powder We have already described the composition of virol of the Virol Company Limited of 152 to 166, Old-street London E.C. It is an emulsion of red bone-marrow malt extract, eggs, lime and lemon juice, and is of value where a special food is required. Close by were the many meat preparations of the Bovril Company, Limited whose offices are on the same premises as are those of the Virol Company Mellin's Food Company of Marlborough Works, Stafford street, Peckham, London S.E. exhibited a well prepared cod liver oil emulsion and a food for infants and invalids. The latter preparation is to be employed with cow's milk the product showing then the same composition as human milk. Messrs. Brand and Co.'s list (of Mayfair London, W) contains a wide choice of beef preparations, including nutrient powder meat juice, beef tea, jellies and so forth A useful variation from beef preparations is the pure mutton essence known as 'hipi and prepared by Messrs. G Nelson Dale and Co. of 14 Dowgate hill, London, E.C. It does not contain merely the extractives of the meat for part of the nutritive albuminous portions are present also

III.—SANITARY APPLIANCES DISINFECTANTS &C

Conspicuous in this section was the exhibition of sanitary appliances for hospital use and lavatories for operating rooms. Messrs. Doulton and Co of Lambeth London S.E. exhibited two types of lavatories the feature about which was that both supply and waste can be actuated without being touched by the hand One is provided with a treadle arrangement while the other is fitted with valves connected with levers which are worked by the elbow The supply valve is so constructed as to give water at any required temperature and the cold supply must be turned on first so that scalding is avoided The exhibit included also a special mortuary table and 'wash down closets The hospital bath on wheels provided with a special brake for keeping the bath perfectly still when in use is also worthy of mention. The British Embalmers Society of 81 Great Ancoats-street, Manchester exhibited a complete set of embalming instruments including a formaldehyde lamp and regenerators for disinfecting purposes. The system consists in injecting into the circulatory system and the cavities a well known powerful antiseptic. An extensive series of antiseptic preparations chief amongst which were creolin and its compounds was presented to view on the stall of the Jeyes Sanitary Compounds Co Limited 64, Cannon-street London E C The interesting disinfectant izal was also shown in many forms, such a fluid powder lozenges, ointment and soap by Messrs. Newton, Chambers and Co. of Thorncliffe near Sheffield. A pleasant antiseptic is eucryl and a number of useful preparations are made with it such as bath eucryl, toilet soap, tooth powder pastilles and so on all proprietaries of Eucryl, Limited, of Sculcoates, Hull. We have already described the emergency disinfector and the Mackenzie spray recently introduced by the Thresh Disinfector Co Limited of 16, Great George-street, London S.W The action of the former depends upon the vaporisation of formaldehyde with steam. The apparatus is effectual and very convenient. The Mackenzie spray is adapted for the disinfection of walls, ceilings and floors of a room of ordinary size Messrs Hendry and Pattison of 11 Hill-place, Oxford-street, London, W exhibited an improved ventilating warm air stove suitable for hospital wards.

Fresh air is admitted to the stove under the floor and passing through a channel in the stove is gently warmed without being burned and thus the circulation of warm air is kept up. A number of filters adapted for many different purposes were shown by the Berkefeld Filter Co , Limited, of 121 Oxford street, London, W As is well known, these filters have successfully withstood bacteriological tests Similarly, the Brownlow germ filter has been shown to resist the passage of germs Various forms of this filter, both for high and low pressure, were shown by Messrs Slack and Brownlow, of Abbey Hey, Gorton, near Manchester Lastly, in this section may be included the oowana soap which is made with special care as regards the selection of the base and fat while *the addition of a fluid* vegetable extract makes it very suitable for delicate skins Specimens of this soap were exhibited by Oowana, Limited, of 205, Victoria street, S W

It will be seen that the representation of this section of the exhibition this year was a relatively small one.

(To be continued)

ROYAL COLLEGE OF PHYSICIANS OF LONDON

AN ordinary meeting of the Comitia was held on Thursday, July 31st Sir WILLIAM S CHURCH, the President, being in the chair

The PRESIDENT announced that Dr David Ferrier would deliver the Harveian lecture for the year and that the Bradshaw lecture would be delivered in November by Dr C J Cullingworth Dr A. S F Grünbaum had been appointed Gulstonian lecturer and Dr T R. Glynn Lumleian lecturer for 1903 and Dr J R Bradford the Croonian lecturer for 1904

The following gentlemen having passed the required examinations were admitted Members of the College —Edwin H Brown, M D Brussels, L.R C P , University of Bombay , Joseph G Emanuel, M D Lond., L R.C P Queen's and Mason Colleges Birmingham , George N Meachen M B Lond , L.R.C P , Guy's , and David W Sutherland, M B Edin

The Bisset Hawkins gold medal was awarded to William Henry Power, F R S , principal medical officer to the Local Government Board.

The following Fellows were elected officers of the College —Censors Sir R Douglas Powell, Dr George Vivian Poore, Dr Frederick Thomas Roberts, and Dr David Ferrier Treasurer Sir Dyce Duckworth Emeritus Registrar Sir Henry A. Pitman Registrar Dr Edward Liveing Harveian Librarian Dr Joseph Frank Payne. Library Committee Dr Samuel Lee Dr Philip Frank, Dr J Wickham Legg, and Dr W H Allchin *Curators of the Museum* Dr W Howship Dickinson, Dr H Charlton Bastian Dr William Cayley, and Dr John Abercrombie

Dr Henry Carr Maudsley and Dr William C Wilkinson, being resident in Australia, were admitted *in absentia* to the Fellowship

The following were selected examiners in the subjects indicated for the ensuing collegiate year —*Chemistry and Chemical Physics* Mr J M Thomson, F R.S , Dr H. Forster Morley, D Sc., F C S Mr Harold B Dixon, F R.S , Dr F D Chattaway Ph D D Sc., and Mr H M Kellas, F C S *Materia Medica and Pharmacy* Dr F Willcocks Dr L C Perry, Dr W E Wynter Dr H A Caley, and Dr F W Tunnicliffe *Anatomy* Dr B C A. Windle and Dr A M Paterson *Physiology* Dr R A Young, Dr J S Edkins, and Dr L E Hill. *Medical Anatomy and the Principles and Practice of Medicine* Dr F de H. Hall, Sir Isambard Owen, Dr S H. West, Dr P Kidd Dr J Abercrombie Dr Nestor Tirard Dr Donald MacAlister, Dr S P Phillips Dr William Pasteur, and Dr J K Fradient *Midwifery* Dr A. L. Galabin Dr G E Herman Dr Amand Routh Dr W R. Pollock and Dr F Mahns *Public Health* Dr A P Luff and Dr W H. Hamer After some formal business the President dissolved the Comitia.

ARMY MEDICAL SCHOOL, NETLEY

DISTRIBUTION OF PRIZES BY THE COMMANDER-IN-CHIEF.

THE eighty-fourth or summer, session the Army Medical School was brought to a conclusion on July 29th, when Lord Roberts distributed the prizes and delivered an address to the surgeons on-probation who had been at the school during the preceding four months. All the probationers were for the Indian Medical Service, no examination having been held for commissions in the Royal Army Medical Corps The Commander in Chief, who was accompanied by Countess Roberts, was received at the Royal Victoria Hospital by Surgeon-General Townsend, the recently appointed Principal Medical Officer At the ceremony there were present the Director General of the Army Medical Service, Surgeon General Sir William Taylor, K C B , Lieutenant General Sir T Kelly Kenny, Adjutant General to the Forces , Surgeon General Evatt, Principal Medical Officer of the 2nd Army Corps , Surgeon General Sir Joseph Fayrer, Bart , K C S I , Colonel Cayley, C M G , the Assistant Military Secretary for India , Colonel W F Stevenson, C B , Colonel W E Webb , the Military Staff of the Royal Victoria Hospital and Army Medical School , and a distinguished company

The prize distribution took place at 12.30 o'clock and was opened by the reading of a report of the work of the session by Colonel K McLeod, professor of military medicine and secretary to the senate of the school Colonel McLeod stated that the work of the session had been most satisfactory 36 of the candidates had passed their final examination and were recommended for His Majesty's Commission Of these 36 officers 32 had been selected after the open competition in London and the remaining four were nominated by the Secretary of State for India after having done good work in India as civil surgeons on plague duty The following list shows the places gained by the young officers and the prizes which the most successful ones received , the smaller number of marks shown against the names of the last four officers on the list is due to the fact of their nomination to the service, for them only the marks gained at Netley are shown

INDIAN MEDICAL SERVICE.

List of surgeons on probation who were successful at both the London and Netley examinations The prizes are awarded for marks gained in Army Medical School The final determined by the marks gained in Netley and the combined numbers are accordingly shown in the list which follows —

July 29th 1902

* Gained the Herbert Prize the Parkes Memorial Medal and the Prize in Pathology presented by Surgeon General Sir William Taylor K C B

† Gained the Martin Memorial Medal the Maclean Prize for Clinical and Ward Work and the De Chaumont Prize in Hygiene

‡ Gained the Second Montefiore Prize of £7 7s

§ Gained the Prize in Pathology

‖ Gained the First Montefiore Prize of £21 and Medal

¶ Gained the Marshall Webb Prize of £5 and Medal.

The Commander in-Chief when presenting the prizes addressed a few words to the prize winners and specially complimented Mr Barnardo on his success and upon the circumstance that he had already seen service in the field in South Africa

Lord Roberts subsequently delivered an address to the young officers He said —

'It is with great interest that I have listened to the report which Colonel McLeod has just read to us and I am much impressed by the statement of the admirable work which has been carried on during the 42 years the candidates for commissions in the Indian Medical Service have been trained at Netley. I quite understand the regret that this is the last occasion on which these prizes will be given away here, but I suppose there can be no doubt as to London being the most suitable place for a training school such as this, and I feel sure the authorities would not have made the change had they not been satisfied that it was necessary. There is no profession which requires more careful training than the one you are about to enter and certainly none in which constant study and research are so absolutely essential. Even in my recollection the advance made in medicine and surgery is very remarkable. A few nights ago I had the honour of meeting Lord Lister and I could not help telling him how deeply indebted we soldiers are to him for his wonderful discoveries. Only those who know what a field hospital was like 40 or 50 years ago can have any idea of what has been effected by the introduction of antiseptics. You are about to join a noble profession and you will find there are grand openings in India for those who keep themselves up to date and who are determined to get on in it. The Indian Medical Service is well paid, the pensions are good, and it affords opportunities in many and varied directions for men of ability and industry to achieve success and distinction. Time will not admit of my speaking to you of all the officers of your service who have distinguished themselves in India, but there are a few whose names I should like to mention. To go back to early days there was a pioneer of the Indian Medical Service, Dr. William Hamilton, who nearly 200 years ago for his successful treatment of the Emperor Farrukshah obtained a grant of land for his countrymen with permission to trade. Then Fryer, Buchanan, and Barnes were distinguished as scientific observers, travellers, and diplomatists. Wilson, Sprenger, and Bellew were noted authorities in geology and palæontology; O'Shaughnessy had a large share in the organisation of the Indian Telegraph Department; Paton greatly developed the Postal Department. Macnamara and Warden were eminent chemists. Russell and Jerdon were great naturalists. Norman Chevers, and Lyons were admitted authorities on medical jurisprudence. Brandis, Cleghorn, King (whose name will always be associated with the beautiful botanical gardens in Calcutta) and many others were noted as botanists; the Goodeves, Sir Ranald Martin, Birdwood, your own head here, Colonel McLeod, and many others that might be enumerated were, or are, eminent as professors and writers on medicine and surgery. De Renzy, James Cunningham, and John Richardson will always be remembered as men who successfully grappled with the sanitary needs of a country in which sanitation is of vital importance. Mouat, Walker, Planck, Lethbridge, and others are identified with the excellence of the gaol system in India. Nor in such an "honours list" must the names be omitted of such men as Campbell, Mackinnon, my old friend John Campbell Brown, and Fayrer, whom I am glad to see here to-day and whose devotion to duty I trust you will all emulate. One other name I must refer to, the late Director-General Robert Harvey, whose life was one long record of activity and usefulness. It was at his instance that the Government of India recently organised a research department for the investigation of diseases, thereby adding another and an important attraction to the Indian Medical Service—a grand field of inquiry, observation, and discovery. I must not detain you longer; I have said enough to show you the unique prospects that are open to you and it only remains for me to congratulate you all on the successful conclusion of your labours here and to express the hope that in the large field which you are about to enter you will bring your best energies to bear and will honourably maintain and, if possible, increase the splendid reputation and the grand traditions of the service to which you now belong. Let me commend the natives of India to your special care and protection. I would advise you to lose no time in learning the language and to do all in your power to cultivate the friendship of the people among whom your lot may be cast. You will be well repaid for any trouble you may take in these respects. There are many able natives in the lower grades of your own profession from whom you will obtain valuable assistance if you treat them with kindness and courtesy.

The Director-General, A.M.S., and Sir Joseph Fayrer then addressed some words of advice to the young officers and the proceedings were brought to a termination by Surgeon-General Townsend, who thanked the Commander-in-Chief for coming to distribute the prizes and for his address. The officers of the Royal Army Medical Corps subsequently entertained the company at luncheon.

METROPOLITAN HOSPITAL SUNDAY FUND

A MEETING of the Council of this Fund was held at the Mansion House on August 5th, when the Right Hon. Sir JOSEPH DIMSDALE, Bart., M.P., Lord Mayor, president and treasurer of the Fund, occupied the chair. Amongst those present were Sir Sydney Waterlow, the Earl of Meath, the Rev. Canon Fleming, Mr. Thomas Wakley, Dr. J. G. Glover, the Rev. Dr. Adler (the Chief Rabbi), Sir William Church (President of the Royal College of Physicians of London), Mr. O. Macnamara, Captain Cundy, Sir H. C. Burdett, the Earl of Stamford, Mr. Alfred Willett, and Mr. F. H. Norman.

The following is the annual general report of the Committee of Distribution:—

The Committee of Distribution [illegible] 202 institutions. The amount of [illegible] the Court of Chancery to the pre[illegible] tion of £57 500 to 147 hospitals [illegible] recommended.

This year 204 institutions, or four more than last year, have made applications for grants from the funds at your disposal. The committee of one old-established hos[illegible] funds, did not seek to participate [illegible] sary to invite the attendance of [illegible] of five [illegible] h your [illegible] no hos[illegible] he two [illegible] th in [illegible] This [illegible] ore to [illegible] ation of [illegible] ace of [illegible] actors [illegible] mount [illegible] dinary [illegible] ted in [illegible] to the [illegible] urchase [illegible] ortions

The LORD MAYOR, in opening the proceedings, said that it gave him great pleasure to announce that in this, the thirtieth year of the Fund, the sum of £60,000 had been collected, and he had every reason to hope that before the end of the financial year on Oct. 31st the total amount would exceed that of any previous year. The collections in places of worship reached the sum of £45,000, an increase of £9000 over last year's total and a record amount. Mr. George Herring's proposal had proved a great incentive to the congregations. Without desiring to make invidious comparisons he would like to state that St. Paul's Cathedral had collected the sum of £2129 as the result of a special appeal which he had made, and Christ Church, Lancaster-gate, in response to Prebendary Ridgway's appeal, had collected the large sum of £1628, while St. Michael's, Chester-square, by the efforts of Canon Fleming, had contributed £1398 to the Fund. Since its inception Canon Fleming's untiring energy on its behalf had resulted in the Fund benefiting by the large sum of £25,000. St. Peter's, Eaton-square, had collected £9[illegible]5, and the church which he (the Lord Mayor) himself attended had contributed £569 towards the general total. Westminster Abbey had not yet sent in the amount collected on Hospital Sunday. While congratulating themselves on the substantial increase in the total collections from places of worship the Lord Mayor said that the Council and friends of the Fund should not forget the very liberal response which is always made by the Jewish community. He specially desired to call the attention of the Council to the fact that there were many beds still unoccupied in several of the hospitals—notably at Guy's and the Metropolitan Hospital, Kingsland-road—and it was worthy of consideration whether donations from the Fund should be given while beds remained unoccupied. He called attention to the recommendation of the Distribution Committee that the [illegible] of the money given to the hospitals [illegible] go towards the maintenance of the patient and not be spent on "bricks and mortar" A large amount of the total sum collected by this fund was subscribed by what he might call the poorer portion of the people of London and the idea of these subscribers was that the money should be spent on the patients themselves. The Lord Mayor concluded by stating how pleased he was that during his mayoralty a record collection had been made, while he expressed his deep regret for the loss which the Fund had sustained by reason of the death of his old friend, Sir Richmond Cotton, and the resignation of Colonel Francis Agar

Sir SYDNEY WATERLOW, in proposing

> That the report of the Committee of Distribution for the year 1902 be and is hereby approved and that the several awards recommended be paid as soon as possible,

said that this was a red letter day in the history of the Metropolitan Hospital Sunday Fund, for after 30 years of the working of the Fund they were able to announce the largest collection that had ever been made He referred to the founding of the Fund in 1872 and the collection which was made in the following year amounting to nearly £28,000 The total collection had year by year increased and there could be no better evidence of the confidence which the public placed in the Fund than this fact The labours of the Distribution Committee had been exceptionally heavy during the past year and there were a larger number of deputations from hospitals received. As yet they had not been able to fix upon a maximum cost per bed in patient in the hospitals, though the matter had received careful consideration.

The Earl of STAMFORD seconded the motion.

Sir HENRY BURDETT, referring to the Lord Mayor's remarks respecting empty beds at Guy's Hospital, asked whether it was not the case that the beds were set apart for paying patients He noticed, he said, that a grant had been refused to the Hospital of Saint Francis, an institution which, in his opinion, was not entitled to the name of 'hospital" He thought that the Council should make a rule that no new institution should be eligible to apply for a grant unless it had first been inspected by someone connected with the Fund

Sir SYDNEY WATERLOW, replying to Sir Henry Burdett, said that representatives of the Hospital of Saint Francis had been invited to attend the Distribution Committee but no notice was taken of that invitation.

The LORD MAYOR also, in reply to Sir Henry Burdett, said that what he meant by remarking that Guy's Hospital had beds unoccupied was that beds had now to be used for paying patients which under other circumstances would be utilised for the poor

The motion was then carried

Sir WILLIAM CHURCH moved —

> That the cordial thanks of the Council be given to George Herring Esq for his continued and generous donation to the Fund which has materially assisted in raising the total collections this year to a record amount.

Canon FLEMING, in seconding the motion, said that the result of this year's collection showed that King Edward's Fund and the Metropolitan Hospital Fund were not antagonistic but really helped each other

The motion was carried.

Dr ADLER proposed, and Mr MACNAMARA seconded, the following motion, which was carried —

> That the cordial thanks of the Council be and are hereby given to Sir Sydney H. Waterlow Bart (chairman) and to the other members of the Committee of Distribution for the care bestowed in the preparation of the awards they have recommended.

Mr ALFRED WILLETT, in proposing

> That the thanks of the Council be and are hereby given to the editors of newspapers who have pleaded the needs of hospitals and advocated the cause of this Fund

paid a special compliment to THE LANCET for the work which that journal had done in the cause of the Fund

The Rev Canon BRISTOE seconded the motion, which was then carried

On the motion of the LORD MAYOR a special vote of thanks was accorded to Sir Edmund Hay Currie, the secretary of the Fund, which was seconded by Sir SYDNEY WATERLOW and supported by Sir HENRY BURDETT, who said that there would not have been a record collection this year had it not been for Sir Edmund Currie The vote of thanks was carried unanimously and briefly replied to by Sir Edmund Currie.

On the motion of the Earl of MEATH, seconded by Mr F H NORMAN the cordial thanks of the Council was given to the Lord Mayor who, as president and treasurer, had devoted his valuable time and influence to the well being of the Fund To this the LORD MAYOR replied and the proceedings terminated.

ARMY MEDICAL REPORT FOR 1900[1]

FIRST NOTICE.

IT is to be regretted that Government publications, upon the drawing up of which great care and labour have been bestowed, attract, as a rule, so little attention There are, no doubt, several reasons why this should be the case. To begin with the number of publications of all sorts in the present day is such that it is extremely difficult, if not impossible, to keep up with them, the shelves and tables of medical and scientific societies groan under the weight of periodical literature Official reports when relating to matters of public health largely deal, moreover, with figures, and the ordinary reader has no taste for anything in the shape of statistics, then official reports are not up to-date in the sense that they often relate to facts and occurrences long preceding the time of their publication and there is, so to speak, no end to their number Be all this as it may there can be no doubt that many valuable reports—such as those of the Sanitary Commissioner with the Government of India, for example—share a common fate in this respect, that they are altogether unread or only referred to by those who are in search of special data or who are specially interested in some particular subject. It becomes a seriously increasing difficulty with journalists desirous of keeping their readers *au courant* with medical progress in this country and abroad to cope with the number of books, periodicals, and pamphlets which find their way to an editor's library table.

To turn from these prefatory remarks however, to the report on the health and sanitary condition of the army for the year 1900 In a volume of some 537 pages we can only pretend to deal with a few of the statistical results and to touch upon a few salient points which happen to strike us.

With regard to South Africa we learn that no annual returns of sick having been submitted statistics for comparative purposes cannot be prepared and we must consequently wait till a medical history of the war has been drawn up

From the excellent general summary of the health of the troops at home and abroad we find that their average strength (exclusive of South Africa), as computed from the returns received by the Army Medical Department, was 226,276 warrant officers, non commissioned officers, and men The admissions to hospital represent a ratio of 827 7 per 1000 on that strength and the deaths one of 9 05 per 1000 on a strength of 247,819, which includes detached men not shown in the foregoing returns

A glance at the tables on pages 4 and 5 of the report will enable the reader to compare the statistical results of 1900 with those of the previous ten yearly periods from 1890 to 1899, only it has to be borne in mind that whereas those for South Africa and St. Helena are omitted in the former they are included in the latter (the ten yearly tables) The results are thrown into tabular form and arranged in columns under different headings in sufficient detail to afford all necessary information for gauging the health of the army Speaking generally the results for 1900 are satisfactory The death rates at Gibraltar and Bermuda occupy a low, and those in China, India, and on shipboard a relatively high, place in the table. Extra hospital accommodation had to be provided for the reception and disposal of 34,452 invalids returning from South Africa during the year and for this purpose Doecker huts, huts of War Office design, hospital marquees, and in some cases hired buildings, were largely used in order to supplement the existing hospital accommodation at numerous military stations and camps in England.

It is satisfactory to notice the continued decline of enteric fever at Bermuda—probably attributable to the replacement of the dry earth system of conservancy by a water carriage system and a careful attention to sanitary detail. Bermuda is a station which offers many facilities for introducing and carrying out a more effective system of sewage disposal than has hitherto existed there. In Mauritius the general health of the troops had improved. There had been no case of plague among the troops, malarial fevers and venereal diseases had declined but the number of cases of enteric fever had increased. Port Louis is the main seat and source of unhealthiness and the troops should as far as possible be located at Curepipe and in the uplands. At Ceylon there had been a marked decrease in the admissions for malarial fevers in 1900 and considerable improvement in the admission rate for venereal diseases.

---

[1] Army Medical Department Report for the year 1900 with appendix Vol. XLII London Printed for His Majesty's Stationery Office by Harrison and Sons St. Martin's lane, Printers in ordinary to His Majesty 1902. Price 2s 3d

In the Straits Settlements the health of the troops had been exceptionally good. More stringent measures, through the instrumentality of a local ordinance lately introduced have been taken with much apparent success in repressing the spread of venereal diseases, and the same may be said in regard to China.

In Egypt the general health of the troops is stated to have been good. With regard to the recent sudden and severe outbreak of cholera at Cairo, we may remark *en passant* that so far as the British troops are concerned the best thing to do is to remove them at once from Cairo to Helouan and the desert, and we are glad to notice that this is being done

In India there was an increase in the death and invaliding rates, but a decrease in the admission and constantly sick rates. The decrease of enteric fever is a notable feature and as we have previously had occasion to point out, might have been expected from the fact that owing to the late war in South Africa and the cessation of the usual reliefs, there has been a decreased supply of susceptible material arriving in India. Of course, there are other things to be taken into account, but we reserve our remarks on this subject for the present. There is much in this report about enteric fever The researches of various experts abroad as well as those of Dr P Horton-Smith and others in this country the remarks in Munson's 'Military Hygiene,' and the labours more especially of the special medical commission appointed by the United States Government to report upon the causes of the great and widespread prevalence of typhoid fever among the American troops during the late war with Spain, have greatly added to our knowledge and have thrown a new and strong light on the etiology and pathology of that disease, especially in relation to its prevalence in camps and armies. The general trend of these investigations is strongly to discredit the correctness of any one and exclusive view of causation, such for example, as that the typhoid fever of armies is solely a water borne disease. But the subject is too large to be discussed in the present article we may however remark that the results and bearing of the American investigations are important and demand attention.

ASYLUM REPORTS

County and City of Worcester Asylum (Annual Report for 1901).—The average number of patients resident during the year was 1174 comprising 527 males and 647 females. The admissions during the year amounted to 246—viz. 113 males and 133 females. Of these 210 were first admissions Mr G M. P Braine-Hartnell the medical superintendent, states in his report that among the patients admitted 165 were in indifferent health and enfeebled bodily condition and 50 were in bad health and exhausted condition The number of patients discharged as recovered during the year amounted to 97—viz. 48 males and 49 females, or 8·26 per cent. of the average number resident. The deaths during the year amounted to 108, or 9 2 per cent. as calculated on the same basis. Of the deaths four were due to renal disease five to epilepsy 10 each to phthisis and cardiac disease, 13 each to senile decay colitis and general paralysis of the insane, 20 to pneumonia, and the rest to other causes. Post-mortem examinations were made in 93 out of 108 cases. Among zymotic diseases which occurred during the year were chicken pox which attacked two male patients, and typhoid fever which affected one male patient. Colitis caused a good deal of trouble by reason of its occurring in irregular outbreaks. "Various methods of treatment [for colitis] much recommended in other asylums were tried but without satisfactory results" The desire to improve the system of nursing in the asylum has led to the introduction of trained nurses in the male wards and the new system is being watched carefully in order to determine whether a more extensive adoption of it would be justified. "The method has been tried in Scotland says Mr Braine-Hartnell and its advocates are loud in their praise. I think we ought to be able to show that the increased cost would give an increased recovery rate before we make such wide and sweeping changes" The Commissioners in Lunacy state in their report that they were able to form a very favourable opinion of the condition of the asylum, that the wards were in excellent order and the day rooms tastefully decorated that the sanitary conditions were generally excellent, and that the medical case-books and records were very well kept. The committee of management states in its report that a cemetery for the interment of patients dying in the asylum was duly consecrated by the Lord Bishop of Worcester in July The maintenance charge per week for patients is 7*s* 7*d* per head which was the same as that of the previous year

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A MEETING of the Council was held on July 31st, Sir HENRY G HOWSE, the President, being in the chair

It was resolved

That 500 copies of vol. II of the Catalogue of the Physiological Series of Comparative Anatomy should be printed

The balance-sheet for the year ending June 24th, 1902, was laid before the Council. The chief points in the accounts are as follows. The gross income of the College for the year has been £26,954 being £850 greater than in the previous year The expenditure for the year amounts to £24 377 The balance of income over expenditure amounts to £2577 if, however allowance is made for the sum of £479 paid for rates due in respect of the previous year it will be found that the income has exceeded the actual expenditure of the year by £3056. During the year the investments of the College have been increased by £3000

The receipts from the Fellowship examination have been just sufficient to defray the out-of pocket expenses

The balance-sheet was approved and adopted.

Mr C. H. Golding Bird was re-elected a member of the Court of Examiners

Mr W B. Paterson was elected a member of the Board of Examiners in Dental Surgery

A report was received from the committee appointed to receive a deputation from the Association of Licentiates of the Royal College of Physicians of London and Members of the Royal College of Surgeons of England, and it was resolved to refer the petition to the Conjoint Committee of the two Colleges recently appointed to consider the possibility of a connexion with the University of London for certain purposes.

A letter was read from the Principal of the University of London thanking the Council for allowing the University to use specimens from the Museum of the College for examination purposes

An application was read from Dr William Stirling Dean of the Medical School of the Owens College, Manchester for permission to have casts taken for that school of the busts of Sir Charles Bell Sir Astley Cooper and John Abernethy

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A QUARTERLY meeting of the College was held on July 29th, Sir THOMAS R. FRASER, the President, being in the chair

The VICE PRESIDENT congratulated the President in the name of the College on the honour of knighthood which had been conferred on him by the King and the PRESIDENT, in reply expressed his gratification at having been the medium through which the College had received recognition from His Majesty

Dr William Blackley Drummond and Dr John Eason were admitted by ballot to the Fellowship of the College.—

Dr G F B Simpson was admitted by ballot to the Membership of the College after examination.

The Secretary reported that since the last quarterly meeting 61 persons had obtained the Licence of the College by examination

The regulations regarding the single Licence and Membership and Fellowship of the College for the ensuing year were approved —The Secretary announced that, in virtue of an alteration of the articles of agreement existing between the College and the Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow the College would henceforth admit Licentiates of the Society of Apothecaries of London and of the Apothecaries' Hall of Ireland to examination for the single Licence of the College

The Queen Victoria Cullen Prize of £100, which is in the gift of the College and is awarded every four years to a Fellow, Member, or Licentiate of the College "for the greatest benefit done to practical medicine," was on this occasion divided between Dr J W Ballantyne and Dr J C Dunlop

The College expressed its concurrence with the recommendation made by the Royal College of Physicians of London that in certificates of death the term "epidemic enteritis" should in future be used in place of "epidemic diarrhœa," and its conviction that the general adoption of this recommendation by the practitioners of Scotland would be highly advantageous in the interests of the public health and of accuracy in the national records of mortality

The President was nominated as a member of the General Committee of the Cancer Research Fund.

The President announced that he had accepted an invitation from the President of the Royal College of Physicians of London to act as a member of the committee for the preparation of the revised version of the official "Nomenclature of Disease"

A report prepared by a committee of the College as to the way in which that part of the Carnegie gift devoted to the advancement of medical science might best be applied was submitted and approved by the College.

The Secretary laid on the table the annual statement by the Governing Board of the School of Medicine of the Royal Colleges in terms of the constitution.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD

On a Localised Outbreak of Enteric Fever at Coventry, by Dr L. W Darra Mair.[1]—The occurrence within a very restricted area of a sudden and severe epidemic of enteric fever at once raises suspicion of pollution of a well or other limited source of water supply, and the outbreak on which Dr Mair reports affords a striking example of the behaviour of a localised epidemic clearly attributable to infection distributed in this way Out of 82 cases of enteric fever notified in Coventry during the third quarter of 1901 no fewer than 60 occurred among the inhabitants of a "blind" street, named Sherbourne street and in courts leading off it. In this small area there are 83 houses, and in 29 of these enteric fever occurred The earliest cases were notified at the end of July, 1901 from "No 4 court" in this area, the epidemic period began towards the end of August and lasted about three weeks, during which time 49 cases were notified from the Sherbourne street area By the middle of September the epidemic had practically ceased. Dr Mair reviews at length the various facts bearing on the outbreak and illustrates the conditions obtaining in the Sherbourne street area by an excellent map. Review of all the facts given makes it certain that the epidemic, as such, was attributable to pollution of a well in No 4 court. The occupants of every house infected at the earlier stages of the epidemic admitted the use of this well water In seven only out of the 29 houses in which fever occurred throughout the quarter was it alleged that this pump-water had not been consumed, and in certain of these seven houses there were reasons for considering the cases to be "secondary" to those in neighbouring dwellings The supply of milk which was common to most of the houses infected was by no means peculiar to the Sherbourne-street area, the same milk was supplied to a larger area outside Sherbourne street in which no exceptional enteric fever occurred. The facts squared with a hypothesis that this well water possessed infective properties during about a week on either side of August 1st, and Dr Mair points to many circumstances which accord with this possibility The well stands at the opening of a small court paved with cobbles or brick, allowing slop water thrown out by the inhabitants to lie about in its irregular depressions The mouth of the well is protected by puddled clay laid on baulks of timber, but in July trenching had been going on in the court and in the neighbourhood of the well, so as to enable the public water supply to be taken to some new water closets being constructed at the end of the court During July also the inhabitants of the court had their closet accommodation much curtailed owing to this proceeding, and opportunities of excrement fouling the surface were increased Add to this that about July 26th the first known case of enteric fever occurred in a house within a few feet of the well and was not removed to hospital, and the further circumstance that a long period of hot weather in July was followed by severe rainfall on July 24th and 27th, during which one and a half inches of rain fell in Coventry, an occurrence specially likely to open up temporary channels in the clay puddling of the well. The surprising part of the story is the hesitation which seems to have been felt locally in attributing this epidemic to its source. Apparently the local authorities adopted the view, which might be thought by now to have been sufficiently often exploded, that the mere fact that chemical and bacterial examination of a particular sample had not afforded evidence of contamination was enough to outweigh strong positive evidence that the water in question had caused disease. In this case a single sample of water collected in September, nearly a month after the well had done the mischief, was analysed by the public analyst, Dr A. Bostock Hill, who reported it to be "of remarkable purity" from the chemical standpoint. A portion of the same sample (no more than 185 cubic centimetres) was examined about a fortnight after its collection by Professor R. F C Leith for typhoid bacillus and bacillus coli with negative results Professor Leith points out that the sample was too small and no doubt he would have preferred a large volume of water sufficient to treat by the far more satisfactory method of filter brushing "The only inference to be safely drawn," Dr Mair points out, from these chemical and bacterial results "is that if the well was polluted about August 1st the pollution no longer existed at the dates when the samples were collected." At most they suggest that exceptional circumstances must have been needed at the beginning of August to produce the specific contamination. But local inquiry showed that exceptional circumstances favouring specific contamination were present in abundance. Dr Mair has occasion to criticise the public health administration of Coventry in certain particulars In this epidemic it was impossible to isolate the sufferers, the system of disinfection at houses, which became, therefore, all the more important, appears to have lacked thoroughness. Good work in the infected area seems to have been done by the Coventry Nursing Institution and by the "female health visitor" employed by the corporation

On Recurrent Prevalence of Enteric Fever in the Folkestone Urban District, and on the Sanitary Administration of the Local Authority, by Dr Theodore Thomson[2]—The problem with which Dr Thomson deals in this report is one of considerable complexity The difficulties met with in obtaining data which justify the attribution of an epidemic of enteric fever to a single cause or collection of causes are often great, and investigations are still more troublesome when it is desired to seek an explanation, not of a circumscribed and pronounced epidemic, but of mere abnormal prevalence of enteric fever sustained over a series of years. In localities where enteric fever is endemic inquiry not infrequently brings out the existence of various circumstances tending to give rise to, and to perpetuate, fouling of the soil surrounding dwellings or fouling of soil water which gains access to wells. The latter explanation is not applicable to Folkestone which has a satisfactory water supply derived from deep wells in the chalk and greensand and notwithstanding certain defects in the sewerage system of the town and faulty conditions of a considerable proportion of house drains the opportunities of pollution of the soil do not appear of themselves sufficient to account for the prevalence of enteric fever While indicating how these defective conditions have probably served to foster the local spread of the disease Dr Thomson is able to point to other factors which have been operative during the period under inquiry This period consists of the years 1896 to 1900 inclusive. For five years before 1896 there had been little enteric fever in Folkestone, the town contrasting favourably in this respect (as had also been the case, judging from the mortality statistics, throughout the 20 years 1871—1890) with England and Wales as a whole. From 1896 onward the incidence, on a population of about 30 000 was at a rate much exceeding that of England and Wales, and the mortality from enteric fever was correspondingly high.

[2] London Eyre and Spottiswoode, Edinburgh, Oliver and Boyd; Dublin, E Ponsonby Price 6d

Year	Deaths from enteric fever	Known cases of enteric fever
1896	4	18
1897	4	40
1898	8	36
1899	16	87
1900	5	50

The report deals with the above cases year by year and for each yearly period eliminates those known to have been imported, or, in other words, to have contracted infection outside Folkestone, and also those in which shell fish were suspected to have played a part. Dr Thomson then proceeds to deal with the question of contaminated milk supplies in relation to each year's history of enteric fever Fortunately accurate observations on this point appear to have been kept by Mr M. G Yunge-Bateman, the medical officer of health of the district, and by his sanitary staff, and the results are instructive. It is only possible here to give a very brief summary of a few of the chief points in each year's inquiry as to milk. 1896 Total cases 18. Group of seven cases in May six of which in four houses, supplied by the same milkman whose total number of houses supplied was about 100 only Group of other seven cases in December, six of which in five houses, supplied by another milkman whose total households supplied was also only about 100. 1897 Total cases 40 distributed more or less throughout the year 14 cases in 13 houses supplied by the milkman implicated in December 1896. 1898 Total cases 36. No evidence sufficient to implicate any one milk supply 1899 Total cases 87 nearly all attacked in September and October 56 cases, in 47 houses supplied by the four milk vendors in Folkestone who sold milk from a particular source AX" One of these vendors A, sold AX milk exclusively Enteric fever occurred in 17 out of the 100 houses thus supplied by him. 1900 Total cases 50, mostly attacked in autumn months. 34 cases in 27 houses supplied by the six milk vendors in Folkestone who in this year sold milk from the source just mentioned AX These six vendors together supplied 800 houses. Again AX milk alone was sold by vendor A at about 100 houses Enteric fever occurred in six of them On the other hand another vendor G also sold AX milk exclusively and in about 100 houses thus supplied by G only one case occurred. AX milk, however was a mixed milk and Dr Thomson shows the probable explanation of the difference between the incidence on A's and G's customers in certain facts which he ascertained with regard to the mixing In 1901 only 14 enteric fever cases several of which were imported" occurred in Folkestone. Facts of the above sort suggesting the influence of milk, receive confirmation from the careful study which Dr Thomson has made of the incidence of the disease each year on age and sex. When the milk factor has been operative a considerably greater incidence on the female sex appears to have been manifest at the same time an observation which accords with previous experience of enteric fever when spread by milk. Dr Thomson points out that the singular feature of these repeated occurrences of enteric fever is that three distinct sources of supply have been implicated in so short a period. He indicates a characteristic common to many of the farm in the Elham and Dover rural districts, whence a large part of the milk supply of Folkestone comes—namely scarcity of water supply leading to the storage of water derived from the surface of roadways or to the use of springs liable to dangerous pollution water in short, derived from anywhere regardless of its quality Conditions of this kind were shown to have attached to the three milk supplies implicated. The report illustrates afresh the care which should be taken not to exclude milk as a cause of infectious disease because various persons attacked are ascertained to be supplied by different vendors. Milk dealers are constantly mixing milks and an instructive feature of this report is supplied by observations which indicate, so far as small numbers can that the amount of disease caused by the implicated milk was in inverse relation to its dilution by other milk.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9183 births and 4018 deaths were registered during the week ending August 2nd. The annual rate of mortality in these towns, which had been 14 5 and 13 9 per 1000 in the two preceding weeks, rose again to 14 1 per 1000 last week. In London the death rate was 13 3 per 1000, while it averaged 14 5 in the 75 other large towns. The lowest death rates in these towns were 4 8 in Hornsey 5 4 in Tottenham 6 8 in Croydon 7 5 in East Ham and Handsworth 7 8 in Reading 8 0 in Coventry and 8 2 in Walthamstow, the highest rates were 19 2 in Hanley, 19 7 in Liverpool 20 4 in Bristol, 21 8 in Bootle, 22 0 in Wigan 23 1 in Gateshead, and 25 3 in West Bromwich. The 4018 deaths in these towns last week included 579 which were referred to the principal infectious diseases, against 558 and 552 in the two preceding weeks, of these 579 deaths 177 resulted from diarrhœa, 118 from measles, 89 from whooping-cough 75 from diphtheria, 60 from fever" (principally enteric) 49 from scarlet fever and 11 from small pox. No death from any of these diseases was registered last week in Reading Devonport, Handsworth Stockport, St. Helens, Barrow in Furness Rotherham or Newport (Mon.) while they caused the highest death rates in Bristol Hanley Liverpool, Bootle, Middlesbrough Stockton-on Tees, Gateshead and Merthyr Tydfil. The greatest proportional mortality from measles occurred in East Ham Bristol Hanley Walsall Rochdale Stockton-on Tees, and Gateshead, from scarlet fever in Hanley and West Bromwich from diphtheria in Bristol, Burnley Middlesbrough, and Rhondda from whooping-cough in West Ham, Portsmouth, and Middlesbrough from fever in Ipswich and Merthyr Tydfil and from diarrhœa in Birmingham Nottingham Liverpool Bootle, Wigan and Gateshead. The fatal cases of small pox registered last week included seven in London two in Liverpool one in Tottenham, and one in Walthamstow but not one in any other of the 76 large towns The number of small pox patients in the Metropolitan Asylums hospitals which had declined from 1515 to 369 at the end of the 14 preceding weeks, had further decreased to 305 at the end of last week, 44 new cases were admitted during the week, against 61, 48, and 23 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday August 2nd, was 2562, against 2352, 2377 and 2486 on the three preceding Saturdays 382 new cases were admitted during the week, against 272, 333, and 397 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 159 155, and 128 in the three preceding weeks, rose again to 135 last week but were 26 below the corrected weekly average. The causes of 49 or 1 2 per cent. of the deaths registered in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Leicester Nottingham, Salford, Bradford Newcastle, and in 48 other smaller towns the largest proportions of uncertified deaths were registered in Hanley Birmingham, Blackburn, Barrow in Furness, Sheffield Sunderland, and South Shield

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 14 7 and 15 8 per 1000 in the two preceding weeks, further rose to 16 8 per 1000 during the week ending August 2nd and exceeded by 2 5 per 1000 the rate recorded during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 9 9 in Leith and 14 1 in Perth to 18 2 in Greenock and 18 9 in Dundee The 535 deaths in these towns included 19 which were referred to diarrhœa, 12 to measles, seven to whooping-cough, four to diphtheria, three to scarlet fever, and three to "fever," but not one to small pox In all, 48 deaths resulted from these principal infectious diseases last week, against 44 and 55 in the two preceding weeks. These 48 deaths were equal to an annual rate of 1 5 per 1000 which was 0 5 per 1000 below the mean rate last week from the same diseases in the 76 large English towns The fatal cases of diarrhœa, which had been 13 and 21 in the two preceding weeks, declined again last week to 19, of which nine occurred in Glasgow, six in Dundee, two in Edinburgh, and two in Greenock. The deaths from measles, which had been 22, 15, and 10 in the three preceding weeks, rose again to 12 last week, and included eight in Edinburgh and three in Glasgow The fatal cases of whooping cough, which had been 15 and 13 in the two preceding weeks, further declined last week to seven, of which four were registered in Glasgow The four deaths from diphtheria corresponded with the number in the preceding week, and included three in Glasgow, where two of the three fatal cases of scarlet fever were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 62 and 80 in the two preceding weeks, declined again last week to 79, but were 14 in excess of the number in the corresponding period of last year The causes of 29, or more than 5 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 20 2 per 1000 in each of the two preceding weeks, rose to 21 2 per 1000 during the week ending August 2nd. During the past four weeks the annual rate of mortality has averaged 19 6 per 1000, the rates during the same period being 14 1 in London and 16 4 in Edinburgh The 154 deaths of persons belonging to Dublin registered during the week under notice exceeded by seven the number in the preceding week, and included 29 which were referred to the principal infectious diseases, against 14 and 15 in the two preceding weeks, of these 18 resulted from measles, five from diarrhœa, two from whooping-cough, two from "fever," one from scarlet fever, and one from diphtheria, but not one from small pox. These 29 deaths were equal to an annual rate of 4 0 per 1000, the death rates last week from the same diseases being 2 1 in London and 1 9 in Edinburgh. The fatal cases of measles, which had been eight in each of the two preceding weeks, increased last week to 18, the deaths from diarrhœa, which had been one and three in the two preceding weeks, further rose to five last week, the mortality from whooping-cough and from "fever" was slightly in excess of that recorded in the preceding week, while from scarlet fever and diphtheria the deaths corresponded with the numbers in the preceding week. The 154 deaths in Dublin last week included 26 of children under one year of age and 35 of persons aged upwards of 60 years, the deaths both of infants and of elderly persons showed a decline from the numbers in the preceding week. Eight inquest cases and six deaths from violence were registered, and 68 or nearly one half, of the deaths occurred in public institutions The causes of six, or nearly 4 per cent of the deaths registered in Dublin last week were not certified.

THE SERVICES

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned Surgeons have been promoted to the rank of Staff Surgeon in His Majesty's Fleet —Henry William Finlayson, Frederick Fedarb, Richard Cleveland Munday Edward Carter Cridland Frank Bradshaw, Matthew Joseph O Regan and Richard Francis Bates

The following appointments are notified —Fleet Surgeon C W Sharples to the *President*, for Deptford Victualling Yard. Staff Surgeons O W Andrews to the *Diana* and R. Hardie to the *Resolution*.

ROYAL ARMY MEDICAL CORPS.

The date of the placing on half-pay on account of ill health of Lieutenant O Challis should be July 5th, 1902, not as stated in the *Gazette* of July 22nd, 1902.

Lieutenant E W Herrington, on relinquishing his temporary commission for service in South Africa is granted the honorary rank of Lieutenant in the Army, with permission to wear the uniform of the corps. Dated July 19th, 1902.

Lieutenant-Colonel P M Ellis is appointed to the command of No 9 Company and to the medical charge of the Station Hospital at Colchester The orders of Colonel G D N Leake to proceed to Colchester to take over the duties of his appointment as Principal Medical Officer, Eastern District, are postponed for the present Captain T P Jones joins at Aldershot for duty and takes over medical charge of the Royal Artillery in Wellington Lines Captain H. Herrick is appointed to the medical charge of the Station Hospital, Satara, as a temporary measure.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain R. Sturling to be Surgeon Major Dated August 2nd, 1902.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers) 1st Lancashire Surgeon Lieutenant F F German to be Surgeon-Captain 9th Lancashire Surgeon Captain A. Cosgrave to be Surgeon Major 1st Warwickshire George Haddow to be Surgeon Lieutenant. 1st North Riding of Yorkshire Surgeon-Lieutenant S Farmer to be Surgeon Captain

Royal Engineers (Volunteers) 1st Aberdeenshire Surgeon Captain J J Y Dalgarno to be Surgeon Major 1st West Riding of Yorkshire (Sheffield) Surgeon Captain C H Willey to be Surgeon Major

Submarine Miners The Tay Division Surgeon Captain G O C Macness to be Surgeon-Major

Rifle The Queen's Rifle Volunteer Brigade the Royal Scots (Lothian Regiment) The undermentioned Surgeon Captains to be Surgeon Majors —A. D Webster and W H Miller 2nd Volunteer Battalion East Yorkshire Regiment Surgeon Lieutenant S H. Johnson resigns his commission. 2nd Volunteer Battalion the Lancashire Fusiliers Surgeon Captain W M. Hamilton to be Surgeon Major 4th Volunteer Battalion the Cheshire Regiment Surgeon Captain G W Sidebotham to be Surgeon-Major 5th Volunteer Battalion the Cheshire Regiment The undermentioned Surgeon Captains to be Surgeon-Majors —J H Hacking and C Averill. 2nd Volunteer Battalion the Royal Welsh Fusiliers Surgeon Major E Williams to be Surgeon-Lieutenant-Colonel. 1st Volunteer Battalion the South Staffordshire Regiment Surgeon-Captain C T Griffiths to be Surgeon Major 2nd Volunteer Battalion the Prince of Wales's Volunteers (South Lancashire Regiment) Surgeon Captain F J Knowles to be Surgeon-Major 6th (Fifeshire) Volunteer Battalion the Black Watch (Royal Highlanders) The undermentioned Surgeon Captains to be Surgeon Majors C E Douglas, C N Lee, J Mackay, and D H Kyle 13th Middlesex (Queen's Westminster) Surgeon Captain P P Whitcombe to be Surgeon Major 2nd Volunteer Battalion the Manchester Regiment Surgeon Captain G H Darwin to be Surgeon Major 5th Volunteer Battalion the Durham Light Infantry Surgeon Captain A. P Arnold to be Surgeon Major 3rd (The Blythswood) Volunteer Battalion the Highland Light Infantry The undermentioned Surgeon Captains to be Surgeon Majors —R. Pollok and A. D Moffat. 1st Dumbartonshire Surgeon Captain J R. F Cullen to be Surgeon Major

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS)

Edinburgh Company Captain D Wallace, C M.G, to be Major. Glasgow Companies George Gordon to be Lieutenant.

BEARER COMPANY

1st Lothian Surgeon Captain A. Macdonald, from the Queen's Rifle Volunteer Brigade, the Royal Scots (Lothian Regiment), to be Surgeon Captain, and to command under paragraph 55A Volunteer Regulations. Surgeon Captain C B Ker, from the Queen's Rifle Volunteer Brigade the Royal Scots (Lothian Regiment), to be Surgeon Captain. Surgeon-Lieutenant A. A. Ross, from the Queen's Rifle Volunteer Brigade the Royal Scots (Lothian Regiment), to be Surgeon Lieutenant

SOUTH AFRICAN NOTES.

The following have been discharged from hospital to duty.—Civil Surgeons Maclean, Pemberton, Tough Miller and McEwen.

SOME SOUTH AFRICAN AND OTHER AFFAIRS

It is much to be regretted we think, that the question of Supply should come up for the consideration of the House of Commons when Members on both sides of the House are wearied and jaded and when the time allotted for the discussion of estimates has to be much restricted. There are a great many matters connected with the Army Estimates as a whole and with the section relating to army medical establishments which we should have liked to have seen more thoroughly threshed out.

There are a few points in the current news connected with the late war which possess sufficient medical interest to be worthy of record. General Lukas Meyer who seems to have been on the whole much gratified with the results of his reception in this country is proceeding to Carlsbad to undergo a course of treatment there before returning to South Africa in November Intelligence received from the Hague informs us of the arrival of ex President Steyn and of his having been visited by Professor Winkler, accompanied by Dr Keuchenius. It is known that Mr Steyn's health as the result of the labours, hardships and anxieties which he underwent during the war completely broke down in South Africa. The exact nature of his complaint has never been definitely stated but we are glad to learn that Professor Winkler and Dr Keuchenius, as the result of their examination, are of opinion that the paralysis of his limbs is due to privations and overwork. They have good hopes of the ex President's recovery, which however naturally will be slow

According to a telegram from Wellington, through Reuter's agency the troopship *Britannic* had arrived there from Durban with 55 cases of sickness on board Three deaths took place during the voyage and one since the vessel came into port. It is alleged that the vessel was overcrowded. No particulars are given but we trust that a searching inquiry will be instituted into the matter and as to the truth or otherwise of the alleged overcrowding

SOLDIERS GUARD BEDS.

We are glad to notice that there is a prospect of something being done at last in the way of improving the beds in guard rooms and that the Secretary of State for War lately in reply to a question by Captain Jessel, has stated that an experimental trial of a new form of bed is being made. Theoretically soldiers on guard are supposed to be always, more or less, on the alert and ready to turn out at a moment's notice, and we must say that the military authorities have done their best to carry this into effect by making the soldier on guard as uncomfortable as may be. It would surely be possible to devise something better than the old pattern guard bed which is a sort of low wooden platform open to various objections in regard to the maintenance of cleanliness, hygiene and personal comfort. Instead of a rigid wooden platform some sort of removeable wire-woven design of a specially durable nature but which was permeable to air might probably be constructed in order to remove or lessen these objections whilst not unduly adding to the comfort of the soldier on guard duty

THE HAMBURG INSTITUTE OF NAVAL AND TROPICAL HYGIENE.

According to the *Archives de Médecine Navale* for June the city of Hamburg has placed 25 beds in the old general hospital at the disposal of the port medical officer for the reception of sailors suffering from internal affections. Hamburg has also been endowed with a hygienic institute, having at its head a medical man nominated by the civic authorities with the approbation of the colonial section The medical officer in-chief has three assistants in whose charge respectively have been placed the departments of clinical medicine, non-clinical research, and hygienic chemistry From 10 to 12 fully equipped tables for research work are to be maintained five of them at the expense of the Empire. It is moreover in contemplation to construct a hospital for sailors to contain 60 beds adjacent to the Sailors Home. The cost of the building is estimated at 120 000 *francs* (£4800)

DEATH OF A CENTENARIAN —The death occurred on July 25th at Bere Heath near Dorchester of a labourer named Winter who had reached the age of 100 years and six weeks.

Correspondence.

"Audi alteram partem."

THE MEDICAL SERVICE OF THE MERCANTILE MARINE

To the Editors of THE LANCET

SIRS,—I have recently spent two and a half years at sea, *serving in five different steamers as ship's surgeon, and I am* bound to confess that £10 a month and all found does seem to me a fair salary except perhaps when there are many steerage passengers. Rank and pay do not correspond on board ships for instance the second engineer ranks below the second officer yet is much better paid Consequently Mr Ogilvie's comparison between the salaries of the surgeon and second officer is beside the point. The second officer is a very hard worked official especially in port and in my opinion really is under paid The surgeon has not much work as a rule and when in port usually goes ashore and has a good time.

If medical men spent, like other ship's officers, their lives at sea no doubt they would be better paid. It is perhaps, fortunate that there is no inducement to stay long at sea, for there is little professional experience to be gained on board ships, and it is, *in fact a lazy life in most cases* I have always been treated by the crew and passengers with the consideration due to a senior officer and by my brother officers as an equal and a friend Once only have I had reason to complain of my cabin and that was soon rectified. With regard to passengers 'fees I find myself more in accordance with Mr Ogilvie. I always refused them myself because I felt that as I had no right to ask for them they were really tips I should certainly advise ships surgeons never to take money from passengers for I know from the many comments that I have heard that the practice does tend to lessen the respect which is the rightful due of the ship's surgeon —I am Sirs yours faithfully

RICHARD KAY M.B Lond.
Late Surgeon to the Peninsular and Oriental Steam Navigation Company

Rochdale August 2nd 1902.

HORSE DUNG IN LONDON STREETS

To the Editors of THE LANCET

SIRS —Mr Beale Collins when writing on the above subject in THE LANCET of July 26th p. 245 says that he has known one or two outbreaks of diphtheria attributable, he thinks to London stable manure but he surely cannot consider this to be pure horse-dung Blood and all kinds of decomposing animal matter get thrown upon manure heaps and I should say that it is to these if anything that the outbreaks of diphtheria he noticed were to be attributed.

I am Sirs yours faithfully

Bexhill-on Sea, July 31st 1902. F P ATKINSON

THE MENTHOL TREATMENT OF PULMONARY PHTHISIS

To the Editors of THE LANCET

SIRS —At a time when the professional and public mind is so largely directed to the question of tuberculosis it may serve some useful purpose to draw attention to a method of treatment of pulmonary phthisis which I have adopted for many years and to which I drew the attention of the profession in my address to the therapeutic section of the British Medical Association at the meeting held here in 1832. In that address I gave a full and detailed description of the manner of the use of menthol in tuberculosis of the lung with cases in illustration and it will be well for those who take an interest—and who does not —in this matter to refer to my paper for full description and directions To some perhaps this may be impracticable so that I may briefly say that the treatment consists of the daily intra-laryngeal injection of one drachm of a 12 per cent solution of menthol in pure olive oil. The results obtained were most encouraging and in some instances unexpected and remarkable. Persons with extensive consolidation, softening, and occasionally cavities at the apex of the lung, after a few weeks' treatment, lost the distressing urgency of cough, expectorated less, were able to sleep, improved in appetite, digestion, and assimilation, and put on weight. It is needless to add that the patients improved the most in whom the disorganising changes and impairment of general health were least pronounced. At the same time careful attention was given to common sense measures for the improvement of the general health by fresh air, nutritious diet of an easily assimilable kind, rest, personal cleanliness, and general hygienic surroundings.

Medically, the drugs used were iron, strychnine, and quinine. Subsequent experience has confirmed me in the value of this method of treatment, and that when the lesion of the lung is not too extensive and the constitutional disturbance is moderate in degree hope of recovery may fairly and reasonably be anticipated. Speaking of constitutional disturbance leads me to observe that one occasionally sees cases where one distressing symptom, dyspnœa, seems altogether out of proportion to the extent of the disorganisation of the lung. Where there are so many facts in medicine it is perhaps unwise—it is certainly often inexpedient—to theorise. But it has occurred to me whether in these cases the bacillar toxins inhibit the heat centres and so, from states of hyperpyrexia, set up the dyspnœa; or on the other hand, may the dyspnœa be more directly caused by reflex through the pulmonary branches of the pneumogastric to an unstable respiratory centre? There is nothing in the method of treatment I now am advocating in conflict with the method described as "the open air treatment." On the contrary, it plays a part—perhaps the leading part—not only in pulmonary phthisis but in all diseases of a malnutritive type. We possess specifics for few diseases and those of us with the largest clinical experience are the foremost to recognise and to emphasise this truth. It behoves us, therefore, to treat disease from a broad and enlightened standpoint. What do I mean by this? Simply that it should be our constant aim and endeavour to balance, so to speak, the discords of disease, to assist the return to the discharge of the natural and healthy functions of the body, to favour a healthy interchange between blood and tissue, to promote a normal metamorphosis—in short, to strive after the attainment of the normal standard, spoken of as health. It is in this direction that healing is accomplished and without it all other means are vain. In this conclusion is nothing new, nothing startling, only the recognition of golden truth revealed by time and observation and the happy possession of men who labour for the good of others.

I am, Sirs, yours faithfully,

JOSEPH O. BROOKHOUSE, M.D. St. And., M.R.C.P. Lond.,
Senior Physician to the General Hospital, Nottingham.

MOTOR BICYCLES.

To the Editors of THE LANCET.

SIRS,—I have followed with interest the letters in THE LANCET *re* motors and as I have during the last five months ridden nearly 2000 miles on my motor perhaps I may be allowed to add my impressions to those you have already published. My machine was built by a local maker (Messrs. Shaw and Co., Bishop Auckland) and fitted with a Minerva engine of 1½ horse-power. Being absolutely ignorant of the principles of mechanics generally I took occasion to visit the workshops during the construction of the bicycle and by the time it was ready for delivery I had acquired a fair theoretical acquaintance with my motor. It was delivered to me on a stormy snowy day in February and so impatient was I to try it that after a trial run which gave every satisfaction I attempted to round a very slippery and rather sharp corner at a rate probably of 15 miles an hour. The machine 'skidded' and I came down. That was my first and, so far, last fall. I have ridden the machine in all weathers, up and down steep hills, through towns, and along back lanes, and up to the present I have nothing but enthusiastic praise for my mount. My battery ran 823 miles without recharging and up to now has only been recharged twice. I am still using the same belt which was on the machine at the start; I have broken it about eight or nine times, but it can be repaired in a couple of minutes and with these exceptions I have had absolutely no trouble whatever.

The machine complete with acetylene lamp, extra large tool bag, and special horn, cost me £42 15*s.* nett. From the point of view of a medical officer of health to a large rural district who has to pay his own travelling expenses this is an exceptionally good investment. Two horses at least would be required to do the rounds I sometimes do in one day, but what I still more prefer is the saving of time. I can easily beat all the ordinary local trains in getting to points of my district and as an effective aid in obtaining the prompt isolation or removal of infectious cases to hospital it is simply invaluable. Within three hours of the receipt of a notification I have had cases *en route* to hospital from houses nine or 10 miles removed from my centre and from very outlying districts, and this without any approach to bustle or hurry. The machine doubtless requires a bit of attention, but everything that is worth having requires attention and well repays it. There is an exhilarating fascination in a good long run on a motor which is quite unlike any other form of pleasurable excitement I have ever experienced and the management of a pulsating, throbbing 1½ horse-power engine underneath one provides constant interest. The battery recharging has cost 1*s.* 6*d.* and the petrol about 20*s.* That has been practically my total outlay in getting over the distance mentioned above. I do not agree with Dr. W. T. Sheppard[1] that those high priced machines made by large firms with names are worth the extra money. I raced a medical man the other day who was mounted on a very expensive and well known motor bicycle (2 h.p.) and I literally romped away from him. I must in fairness add that he was five stones heavier in weight but against that he had an extra ½ horse-power and he has had quite as much experience of motor bicycling as I have.

From my own experience I have no hesitation in advising any one who contemplates buying a motor bicycle to do so. A more economical, rapid, and pleasant way of getting over the ground will be hard to find.

I am, Sirs, yours faithfully,

A. O. FARQUHARSON, B.Sc., M.D. Glasg., D.P.H. Cantab.,
Medical Officer of Health, Auckland Rural District.

July 31st, 1902.

GOLD MINERS IN THE TRANSVAAL.

To the Editors of THE LANCET.

SIRS,—I have read with interest the very timely article of Professor T. Oliver in THE LANCET of June 14th, p. 1677, and would ask a little of your space for some remarks which arise from thinking of the article. Undoubtedly a large number of cases of pulmonary disease have arisen in the Transvaal and in South Africa generally. I believe that Professor Oliver is right in regarding these cases as pulmonary fibrosis. I have seen and observed for weeks many such cases and all bear the clinical features described by Professor Oliver.

I do not desire at present to say anything further of the disease, but I do want to ask medical men in Britain, in the mining districts especially, to warn any miners who have the slightest tendency to pulmonary weakness against coming to South Africa to ply their trade. Following the cessation of the war and the consequent opening of the country, large numbers of men, especially those who have any weakness of the chest, will be for coming here, thinking they can get health and good work. This country and the two newly acquired States are the worst places such miners could seek if they have any pulmonary trouble. Hundreds came out prior to the war and from among these are the patients Professor Oliver, Dr. James Anderson, and others have seen on their return to England since the war began.

Broken down utterly in health after only a short time here, they are terrible examples of the effects of mining in South Africa on any but the strongest constitutions. Furthermore, men who get sick out here cannot get the nursing, care, and attention their cases require, and after battling with the disease they are forced to give in, they start for England and the sea voyage with its quickly varying climates, puts the final touch to them. It is an absolute fact that these cases of fibroid phthisis do very badly on the passage home. I have seen at least 20 of these cases leave Cape Town during the past two years, and their condition on landing in England was very much worse than when they embarked in spite of every care and attention during the voyage. I would therefore ask my professional brethren in Great

Britain if they are consulted by miners to warn them against South Africa and to strongly advise them that the miner to stand any chance here, must have perfect health, for not having this any who come to work in the mines come to certain death. I am Sirs yours faithfully

Cape Town July 8th 1902. THOMAS MARSHALL.

A NEW METHOD OF KEEPING IN APPOSITION THE EDGES OF SURGICAL INCISIONS AND WOUNDS IN ORDER TO PROMOTE UNION

To the Editors of THE LANCET

SIRS —Absence prevented me replying to Mr Haydn Brown s letter of July 12th before now and surely an answer is needed. The inventor who resorts to planetary motion as an explanation of the mode of use of a suture is beyond me Let me repeat on my unpretentious level Who are the surgeons of highest rank who recommend this suture? If one such be named who can fairly assert that the suture possesses one novel point of utility over my clumsy" invention of 18 years ago I shall send you any donation in my power towards any cause you name.

I am, Sirs, yours faithfully

Finsbury Pavement E C August 4th 1902. J MACMUNN

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT)

The Plague Epidemic — Kala-azar" in Assam —The Work of the Lady Dufferin Hospitals for Women.— Inoculations for Cholera and Plague in Bengal.

THE small mortality from plague now occurring has greatly diminished public interest in the disease. In the whole of India there were only 1158 deaths during the week ending July 12th. The minimum mortality of the year—viz 1050—seems to have been reached in the previous week The figures in detail are Bombay Presidency 717 , Punjab 95 Mysore, 214 , Bengal districts, 8 and Calcutta, 20 Bombay city now records fewer deaths than at any time since the commencement of the epidemic. On the other hand there has been an increase in the Bombay districts and in the Mysore province—areas in which the earliest signs of a recrudescence may be expected to occur

The disease known as kala azar" which has for many years been raging in certain districts of Assam and upon the pathology of which there is still so much doubt, has markedly declined in the two chief districts of the Brahmaputra valley most affected There were 5856 deaths recorded for last year It is interesting to note that while this disease declined the mortality from fever increased The district of Nowgong has decreased in population by 86 147 during the past 10 years and it is estimated that 54 000 have succumbed to kala azar The disease has recently spread and effected a lodgment in Sylhet. The unsatisfactory part of all reports from Assam is that as registration is not compulsory except in municipal areas and in tea gardens so little reliance can be placed on the return and this applies more to the Brahmaputra valley perhaps than to other districts. I learn from a recent report that inoculation for small pox is still practised in outlying villages of the Sylhet district and that vaccination generally in Assam has not been very successful.

The administration of the Lady Dufferin Hospitals for Women has come in for some apparently undeserved criticism. While it is true that in some districts comparatively few purdah women avail themselves of the hospitals the general results of the fund are satisfactory The cry that men have control and that the workers are not confined to women is grossly exaggerated. In some of the hospitals they have had to call in the assistance of the civil surgeons but in the main the work is carried on solely by women. There are 40 lady doctors engaged of whom 14 are English. Many of the others though educated in India, have taken degrees in Europe. The fund is not rich enough to engage English ladies in larger numbers The fund relieved the sufferings of one and a half million women last year and through Lady Curzon s influence about six lakhs were collected last year chiefly for the special object of training midwives Many prejudices have still to be overcome. There are many purdah women who consider it a disgrace to enter a purdah hospital and in Rajputana the women consider themselves defiled by touching the hands of an English lady

From the report of the Sanitary Commissioner for Bengal I find that inoculation for cholera has lamentably fallen off This does not appear to be due to any decline in its value but to the fact that even in the tea gardens it is now entirely optional. It is almost entirely confined to emigrants Inoculation for plague is equally under a ban In Calcutta only about 40 inoculations were done during the whole year while through personal influence it met with considerable success in Gaya. The Sanitary Commissioner rightly argues in favour of inoculation as against disinfection, but higher authorities are unable to accept his arguments.

Calcutta, July 17th

THE
SHONE SYSTEM FOR THE THOROUGH VENTILATION OF SEWERS AND HOUSE DRAINS

(BY OUR SPECIAL SANITARY COMMISSIONERS)

MUCH has been said and justly said in regard to the benefits which have resulted from the abolition of cesspools of the pail system and other such contrivances A considerable reduction in the rate of mortality has been attributed to the introduction of general drainage schemes Nevertheless, we have not reached perfection and we can only boast of having substituted a lesser for a greater evil. Experience has taught that if sewers are better than cesspools they have also their evils Sewers were to save our dwellings from all the dangers and inconveniences caused by cesspools, portable pails middens, &c. Hardly however had the system of water-carriage drainage been introduced on a large scale than our sanitary engineers plumbers, and others had to exercise all their ingenuity so as to protect our homes from the sewers themselves. Consequently traps were devised, and these were at first clumsy contrivances which of late have been much improved But now we have to admit that even the best of traps may of itself become a nuisance. The sewer has saved us from the cesspool the trap protects us from the sewer but what shall protect us from the trap? Theoretically of course the flow of air should be through the house-drains to the sewer but in practice the reverse not infrequently occurs. If the water-seal in the traps prevents such currents entering the house the effluvia from this water must travel upwards Of course, if the traps only contained clean water no harm could ensue but these traps especially the larger intercepter traps at the base of the house and separating the house from the public sewer often contain soil and if they are not frequently and copiously flushed they must give off dangerous effluvia At best these emanations are conducted by a ventilating pipe to the roof of the house But this is not satisfactory It is sometimes noticed that smoke will descend a chimney in which there is no fire. This smoke comes from another chimney The difference between the indoor and outdoor temperature causes a down current and thus a chimney will bring into a room the atmosphere from the roof of the house a fact that becomes visible when that atmosphere happens to be charged with smoke Other portions of such atmosphere enter by the windows especially those in the upper part of the house The odour of a chimney on fire only escapes from the top of the chimney yet it is detected by persons low down in the basement of the houses or in the street. It cannot be said therefore, that the air from the sewers or drains will not enter the houses because it has been discharged above the roofs and especially so when it happens, as is often the case that one house is lower than its neighbour The only absolutely satisfactory solution of the problem would be the adoption of a system by which the air in the house drains would have no means of escape except into the sewer

Nevertheless and even if this principle could be rigorously applied it would only transfer the problem from the house and its private drains to the public sewer Now it is generally recognised that as yet no satisfactory method of sewer ventilation has been applied It is easy enough to produce a current of air in a sewer, but these currents travel along the line of least resistance and it is precisely where there is the most resistance that ventilation is most needed Too often we get the ventilation only where it is not so urgently needed Numerous mechanical and other ingenious contrivances have been devised and tried Heat produced by Bunsen burners placed under plaques of fire clay not only attracts a strong current, it was also thought that the heat would purify the sewer air But whether the motive power be that of a furnace or merely difference of temperature or the special construction of a shaft, a chimney, a cowl, or mechanical appliances such as a revolving fan, the result is always the same The air is drawn into the sewer from the largest and nearest apertures and rushes out by the ventilator The more distant parts of the sewer and the branch drains are scarcely affected So long ago as Feb 12th, 1887 we published a notice in THE LANCET of an ingenious invention patented by Mr R S Ash who proposed to ventilate sewers by concussion He argued that the current of a river may run rapidly, yet there are nooks and recesses in the embankment where a boat may be moored and where it will not be affected or borne away On the other hand, if a concussion is produced by throwing a stone into the water, the waves or ripples resulting will travel up every creek or opening in the embankment Mr Ash therefore constructed a cylinder to be placed in manholes and in this gas accumulated and was from time to time automatically exploded Such explosions would not only blow the air out of the manhole but produce a current of air rushing up from the sewer A shock, it was argued, does not travel in a straight line but in ever extending circles and therefore it would disturb and move the air in the branch sewers and drains as well as in the straight line of the main sewer Both theory and apparatus were ingenious and some experiments were made in one of the manholes of the sewers of Monaco But probably the invention did not work out as well in practice as in theory, for nothing more has been heard about it Nevertheless, it was a typical illustration of the difficulty of sewer ventilation

Practically it cannot be said that sewers are ventilated in a systematic and scientific manner Street gullies or man holes act as ventilators and they serve both as inlets and outlets Here and there a special shaft is built or a pipe is carried up a neighbouring wall Nobody knows how much air enters or leaves the sewer, but there is evidence to show that typhoid fever has ensued when street gullies have been sealed and no other apertures for ventilation have been provided in their stead. On the other hand, both man holes and gullies sometimes give off bad odours, but it is better to endure such nuisance than to check the ventilation of the sewers It is a well established fact that sewers ought to be ventilated but the question as to what constitutes efficient ventilation and how this is to be obtained has never been clearly answered Even when the air in a sewer is kept in constant motion and is so frequently renewed as to be fairly pure, this has only a very partial effect on the branch and domestic drains Apprehensions are constantly expressed with regard to sewer air, but when a soil pipe leaks or a trap is defective it is not only the sewer air that enters the house, it is also and primarily the air from the domestic drains and the branch connexion between the house and sewer Here the ventilation is at its worst It often happens that the intercepter is not ventilated so that the drain from the house to the sewer becomes a cul de sac It discharges into the sewer as much foul air as there is water coming from the intercepter trap, whereas there should be a continuous through current In the rare cases where the sewers are self-cleansing and sufficiently ventilated it does not follow that the branch drains are also self-cleansing and efficiently ventilated. The sewer is in the middle of the street and at some distance from the houses, the branch drains go up to, and generally pass under, the houses It is, therefore even more important to ventilate the branch drains than the sewers The traps especially the intercepter traps require particular care, otherwise they will degenerate into small cesspools

Having stated the problem in its broad and general lines the proposals recently made for its solution may now be considered For the first time a scheme of sewer and drain ventilation which professes to be absolutely perfect has been devised But in using the word perfection it is first essential to define what constitutes perfection For this purpose it is necessary to estimate first how much fresh air should be introduced into the sewer per head per day and, secondly, to demonstrate not only that this amount of fresh air can be supplied but that it can be evenly distributed throughout the whole system and especially in the smaller branch drains Messrs Shone and Ault claim to have solved this arduous problem First dealing with the volume of fresh air needed they base their calculation on the experiments made by Dr Letheby who showed that one gallon of putrid sewage gave off 1 2 cubic inches of gases per hour All sewage is not putrid, but taking matters at their worst there still remains the important fact that of the 1 2 cubic inches of gas evolved per gallon of putrid sewage about 90 per cent. is harmless Dr Letheby gives the proportions of the various gases evolved by a gallon of sewage in the course of nine weeks as follows marsh gas, 73 833 per cent., carbonic acid, 15 899, nitrogen, 10 187, and sulphuretted hydrogen, 0 081. Calculating the normal flow of sewage at 30 gallons per day per head it is proposed to supply per minute half a cubic foot of fresh air to every house drain or one tenth of a cubic foot of air per inhabitant. This would dilute the 1 2 cubic inches of sewage gas coming from each gallon of sewage 43,200 times, leaving slightly less than one fourth of one part of such effluvia in 10,000 parts of the air in the sewer By these and other calculations the conclusion arrived at is that one half of a cubic foot of fresh air per house of five inhabitants will more than suffice to dilute the effluvia from foul, putrid sewage, though, as a rule, we have to deal with fresh and not putrid sewage.

Having thus ascertained the maximum amount of air needed to meet the worst conditions the next question is how to obtain this quantity in a constant and trustworthy manner For this purpose it is no use whatsoever relying on atmospheric conditions, on ventilating shafts and on cowls. These must ever be irregular in their action. Every change in the direction and velocity of the wind or of the temperature will modify the velocity of the currents induced. A trustworthy and constant result can only be obtained by the use of machinery A ventilating fan can be regulated to supply exactly the volume of air required Every revolution of the fan propels forward so many cubic feet of air Given a sufficient number of fans revolving at the necessary velocity and the requisite amount of air needed is obtained independently of all atmospheric conditions The fan which Messrs Shone and Ault propose to employ is known as the "Sirocco" and is made by Messrs Davidson and Co of London and Belfast. Its diameter is only seven and a half inches and it can deliver 1500 cubic feet of air per minute, the suction on the one side of the fan being estimated at one inch of water gauge and the pressure on the other, or outlet side, also at one inch, making two inches in all. Such a fan would suffice for a population of 15,000 and if worked by electricity at 3*d* per Board of Trade unit would cost £88 7*s* 6*d* per annum, or £5 17*s* 10*d* per 1000 of the population, or 1 41*d* per head per annum. Of course, water, steam, compressed air, and any other motive power can be employed

It is something to have established the amount of air required and to have shown that this can be obtained at a very small cost by mechanical means But there remains the far more difficult and it must also be said the far more expensive side of the problem Indeed, as already stated, there has never been any great difficulty in setting up a strong current of air in a sewer, the difficulty is to direct and to diffuse that current and, above all, to make it penetrate into the branch sewers and house drains. For the scientific ventilation of assembly rooms and other buildings doors and windows must be closed Air must enter only by specially contrived and measured inlets So, also for the sewers, every manhole, every street gully, and all the old ventilating pipes and shafts must be closed The sewer and its branches must be as air tight as possible No air must enter except where it is controlled and measured Otherwise how would it be possible to know what is being done and to do what is needed? With sewers of ascertained capacity, with a known population discharging a given quantity of sewage per day, it is a matter of calculation to estimate the amount of cubic feet of air that will be required per day or per hour Where, then, should this air be admitted? Evidently it would be very advantageous to admit the fresh air just at those points which in the ordinary course it is least likely to reach Those, as already explained are the branch sewers and domestic drains Thus it is proposed that the domestic soil pipe shall be the air inlet. But in the ordinary course such inlets would occasionally become outlets and already to prevent this mica flap valves are used. They are, however delicate and always get out of order Therefore a protecting cover is placed over the aperture and across there is a non-corrodible wire-gauze screen. Thus leaves, paper large particles of dust, and other objectionable matter cannot enter and interfere with the working of the flap valves within. The pivots of the valves are made of delta metal or phosphor bronze, the seatings of brass or aluminium alloy and the valves themselves of aluminium. This gives rigidity and strength with a minimum of weight Any reversion of the current of air would close these valves and thus prevent the inlet becoming an outlet. This, however is only a mechanical improvement on contrivances for air inlets that have existed and been in use for many years. The converting of every soil pipe into an inlet ventilator armed with flap valves to prevent their becoming outlets would not of itself solve the difficulty If every other aperture was closed and if by the revolutions of the mechanical fan the necessary volume of air was drawn into the sewer still the greater part of the sewer and of the branch drains would not be efficiently ventilated. It would simply mean that far more air would be drawn in through the inlets nearest to the fan than was required while further off there would be little or no ventilation The object, on the contrary is that every soil pipe and every part of the sewers shall be washed by the necessary quantity of air however far it may be from the fan. Therefore, the amount of air that enters the openings nearest to the fan must be checked so that they shall not admit more air than those that are a long way off For this a vulcanite screw plug is fixed into the inlet orifice. This inlet is of the same size throughout and all the plugs fit into all the inlets. These plugs can be changed with the same facility as removal of a screw stopper from a bottle. In the centre of the plug a hole is pierced and it is through this hole that the air passes. Thus the volume of air that enters can be altered according to the diameter of the perforation made in the plug used. Those that are placed nearest to the fan have apertures of only one-eighth of an inch in diameter but there the air travels with considerable velocity The openings are made larger and larger the greater the distance from the fan. By means of the water gauge it is easy to calculate the vacuum produced within the sewer by the air-extracting action of the fan and then the area of aperture can be adjusted at each point according to the vacuum available. The fan connected with a group of drains and sewers has to be placed in such a position that the friction due to the passage of the air shall be equally distributed throughout. So that the amount of vacuum necessary should not be so great as to force the traps connected with the drains the distance effected by one fan should not be very extensive. The vacuum should not exceed one inch of water head as shown by the water gauge. Calculations have been made and tables drawn up indicating at a glance what must be the diameter of the aperture in the plug according to the vacuum in the sewer and the distance of the inlet from the fan. There is no difficulty in the application of these rules and we should then have the same volume of air per head of the population travelling from every soil pipe down into the sewer and away to the fan Though it is estimated that one tenth of a cubic foot of fresh air per head per minute would suffice, there would be no difficulty whatsoever in largely increasing this supply The great point is that the supply should be accurately measured, that the amount should be known that it should be evenly distributed throughout the whole system, that it should enter by the house drain, and travel in the same direction as the sewage. Messrs. Shone and Ault have an installation at No. 20 Victoria street, London S.W. where they show how by the above means, these ends are attained

In all such schemes however it is most essential to provide for accidents or for the abnormal conditions that occasionally arise. For instance the sewer may be accidentally blocked. All the drains and sewers between the fan and the blockage would then be subjected to an increased vacuum unless the rapidity of the fan's revolutions was reduced in exact proportion and at the very moment the accident occurred. If not the vacuum may be so great that it will force the house-trap To prevent this a second flap valve is placed near to the ordinary and measured inlet valves This is a vacuum relief valve and is so weighted that it will not open unless the fixed maximum of vacuum is exceeded. Then the relief valves open and let in more air till the vacuum is reduced to its proper proportion. On the other side of the blockage the ventilation could be partially or wholly stopped. Instead of an increased vacuum the gases arising would produce a pressure from the sewer and drains outwards. If this pressure is very strong it could force the traps and discharge the sewer air inside the houses Therefore a weighted outlet flap valve is also provided which would yield and open to a pressure less than that required to force the traps and let the compressed air from the sewer out into the open instead of its gaining admission inside the houses Again and without there being any accident causing a blockage in the sewers, the ventilation of the house drains may be momentarily stopped where heavy rainfalls are admitted into small sewers. The rise of sewage and rain water in the sewers would then submerge the house drains and the air within them might be so compressed by the heading up of the water as to force the traps. But here again the outlet relief valve would prevent this occurring The street gullies would be treated in the same manner as the house drains they would be provided with similar inlet ventilators and safety relief valves in case of accidents but they would be sealed so as to prevent the sewer air escaping into the streets when the system worked in the normal manner Thus and excepting in the case of the sewers being choked up with water during a storm or blocked by an accident there would be no escape of sewer air into the streets through manholes or gullies or up ventilating pipes on to the roofs of the houses and down chimneys and into open bedroom windows. All the sewer air would go to the fans. These would be very few in number as compared to the existing apertures through which sewer air is allowed to escape. Consequently it would involve but a comparatively small cost to provide at these fan stations a lofty shaft so that the sewer air might be discharged at a safe distance from habitations and rendered harmless if necessary Besides the sewers would be so well ventilated and the effluvia from the sewage so largely diluted by the fresh air drawn into the sewers that it would not be likely to cause a nuisance when liberated into the open atmosphere.

To recapitulate and to sum up this new system, it is proposed to draw into the sewers by mechanical means at least one tenth of a cubic foot of fresh air per minute and per inhabitant Every street gully and domestic soil pipe is to be provided with an inlet apparatus. The aperture of these inlets will be so measured as to facilitate or to restrict the inrush of air in proportion to the vacuum or force of suction within the sewer and thus the right amount of air will enter at every point. Further there will be two sorts of safety valve—one to let air out of the sewer should pressure from within exceed the water gauge of one inch and therefore endanger the seal of the house traps and the other to let more air down into the sewer should the vacuum or suction within the sewer likewise endanger the house traps by exceeding one inch as measured by the water gauge The three flap valves employed for these three different purposes are admirably made and may be described as scientific instruments yet though so delicate in action they are strong durable, and not expensive. Altogether the system seems to us to promise a satisfactory solution of the entire problem by applying a method the efficacy of which can be scientifically tested at every point of the sewers thus treated in a manner never before possible

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Small-pox

DURING the week ending August 2nd there have been six cases of small-pox reported in Swansea, two in Merthyr Tydvil, one in Aberdare three in Neath, and one in the Rhondda valley The Merthyr patients are two children who had been travelling from town to town with a woman who was subsequently discovered at Aberdare and found to be in the second week of the disease Each of the districts affected is provided with isolation accommodation

Pauperism in Wales

A return has recently been issued by Mr F T Bircham, the Poor law inspector for Wales, comparing the amount and the cost of pauperism in the various unions of the principality On March 31st 1902 the percentage of pauperism to population in England and Wales was 2 1 in the whole of Wales 2 7, in North Wales 3 1 and in South Wales 2 6 In the agricultural districts of Bridgend and Cowbridge the percentage was only 1 4, in the mining districts of Pontypridd 1 8 and of Merthyr 2 2, while in the urban districts of Cardiff it was 2 4, and of Swansea 3 2 The largest amount of pauperism was found in North Wales, where in the Holyhead union the percentage was 3 8 and in the Anglesey union it was 4 1 The average weekly cost of each pauper during the year ending March 31st 1902, was 2*s* in the Bridgend and Cowbridge unions, 2*s* 3*d* in Pontypridd, 2*s* 9*d* in Merthyr, 3*s* in Cardiff, and 2*s* 4*d* in Swansea. It will be noticed that except in the case of Swansea the relative positions of the unions is the same whether the percentage of pauperism to population or the average weekly cost is considered

Medical Appointments at the Swansea Hospital

The junior medical appointments in Swansea do not attract many applicants It is not so very long since there was some difficulty in obtaining a resident medical officer for the workhouse and for the position of resident medical officer at the General Hospital about to become vacant there were only two applications received The hospital contains 130 beds and the salary of the medical officer is £75 per annum. The inadequacy of this remuneration may account for the paucity of candidates for the post.

Compulsory Removal of Small pox Patients

Allusion has already been made[1] to the conviction of a man at Swansea who had refused to obey an order of the Swansea justices for the removal of his child to the small pox hospital and on July 29th the defendant appealed to the Court of King's Bench to set aside the decision of the justices His contention was that the child in question was suffering from chicken pox, although he admitted that three other cases of small pox, one of which terminated fatally, occurred subsequently in the same house, and also that insufficient evidence was tendered at the police court proceedings Mr Justice Bigham and Mr Justice Darling upheld the order of the magistrates and the former said that the order for the removal of the child having been properly made the defendant had no right to resist its execution

British Dental Association

In his address to the members of the Western Branch of the British Dental Association at the annual meeting held at Ross on Wye on July 25th the president, Mr S Greatrix Yates dwelt with some emphasis upon the ever increasing prevalence of dental caries and urged the absolute necessity for providing conservative dental treatment in all State institutions, especially where children are under compulsory restraint in reformatories and in asylum He also suggested that prisoners serving beyond a certain sentence should be able to claim skilled dental services

Brentry Home for Inebriates

In order to place this institution in a sound financial position the managers have appealed to the 23 authorities which originally contributed to its support for further assistance, guaranteeing to those who respond a permanent interest in the home The Somerset county council voted £250 only on the casting vote of the chairman, and on July 29th the Bristol town council upon being asked to vote £500, decided to defer the matter for three months with a view to further inquiry as to the results following the establishment of the home The Bath and Bristol corporations are the only authorities who have not yet come to any decision as to the further support of the institution

Phthisical Patients at the Bristol Workhouse

The question of providing suitable accommodation for phthisical patients has been discussed by the Bristol board of guardians upon several occasions during the past 12 months and several proposals have been brought forward. The adaptation of a large house surrounded by extensive grounds at Clevedon met with some favour but the scheme was finally abandoned and at the December meeting of the board it was decided to set aside a ward at the Stapleton workhouse for 30 male patients and to send to special institutions suitable cases, but it was felt by many members that the matter should be dealt with in a much broader manner, one guardian suggesting the purchase of land on the Mendips and the erection of properly planned buildings On August 1st the board finally decided to provide a one storey building to accommodate 40 patients on land at Fishponds in the city The building, which is to be constructed of wood and iron, will include four wards, each 60 feet by 15 feet, three being provided with open balcony fronts, a dining room, kitchen, nurses' rooms, bath rooms, and offices The cost is estimated at £1305

August 4th

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Epidemic Measles in Dublin

THE last meeting of the council of the Dublin Sanitary Association took place on July 26th, when the returns of the Registrar General for the week ending July 19th were considered It appeared that 196 cases of measles were notified during that week in the city while the admissions to hospital numbered only 28, the inference being that the sufferers from the epidemic had been treated chiefly in the houses of the sick A letter was received from the public health committee in reference to this matter stating that it approved of a former resolution of the association suggesting the advisability of a special staff of nurses to visit the children of the poor 'for whom hospital care is not available" and that it was being acted upon

A Vaccination Case

At the Belfast police courts on August 4th the Belfast board of guardians summoned a man who was a Poor law guardian (a representative of the Trades Council) for failing to comply with the vaccination laws in respect of his two children. The charge having been proven the defendant said that he did not intend to obey the law and he was fined £1 and 12*s* 6*d* costs, the chairman remarking that the magistrates were of opinion that the defendant was abusing his position as a Poor law guardian in regard to this matter Objectors to the vaccination of their children are very few in Ireland, the "conscientious" individual towards whom Mr Balfour in his English Bill showed such a weak yielding not being much in evidence As one of the Belfast local papers fairly puts it, the person fined in the above case "is a member of the board of guardians who are the authority for putting the vaccination laws into operation, and he therefore cannot be treated as an ordinary offender against these laws" Ireland, fortunately, is not subject to the "conscientious objection" clause

Formation of a Branch of the Irish Medical Association for the County of Cork

A meeting of the members of the Irish Medical Association residing in the city and county of Cork was held for the purpose of forming a branch for the county of Cork. The following officers were elected —President Dr Jeremiah Cotter, Cork Vice President Mr P O Donoghue, Macroom. Honorary treasurer Mr W Bennett, Clonakilty Honorary secretary Dr D J Flynn, Cork It was decided to issue a circular setting forth the benefits conferred on Irish Poor law medical officers by joining the Association

August 5th

PARIS

(FROM OUR OWN CORRESPONDENT)

Schools of Colonial Medicine

LAST year it was suggested that a chair of Colonial Medicine should be created in the Paris Faculty of Medicine and considerable sums were collected for the purpose by subscriptions but the scheme had to be abandoned as in the Paris hospitals there was little prospect of the admission of patients suffering from yellow fever or other diseases peculiar to the colonies A request by the city of Bordeaux that such a chair should be created in that city has been granted and Bordeaux now possesses a civilian school of colonial medicine. The city of Marseilles under the influence of a similar spirit has now prevailed on the Minister of War to make it the seat of the military school of colonial medicine and has placed at his disposal the magnificent buildings of the Pharo situated on a rising ground at the entrance of the harbour It would hardly be possible to find a place better suited for the purpose. A large theatre suitable for lectures is already in existence at the Pharo Military medical officers about to proceed to the colonies will find in the hospitals of Marseilles patients who have returned home suffering from the effects of every form of disease incidental to the colonies. The botanic gardens of the Parc Borély are very rich in colonial plants. Marseilles also has a very fine colonial museum superintended by M Heckel and Dr Queyrel The authorities have directed that the fitting up of the new school of medicine shall be proceeded with energetically so that lectures may begin in October The money which was subscribed for the creation of a chair of colonial medicine in Paris and which has been hitherto unused has just been made over to the Hôpital des Dames Françaises at Auteuil for the Institute of Colonial Medicine which has now been established there. At a recent meeting of the council of the faculty Dr Brouardel professor and honorary dean in the Faculty of Medicine, was appointed director of this institute Professor Wurtz will deliver lectures on colonial hygiene and epidemiology

The Microbes of Dysentery

At the meeting of the Academy of Medicine held on July 15th M Chantemesse described the nature and action of the two principal factors in the production of dysentery Dysentery either epidemic or sporadic wherever it may break out is due he said to microbes of which there are two completely distinct kinds—one an amœba and the other a bacillus—growing in the intestine Amœba dysentery is sporadic rather than epidemic and is especially prone to attack male adults. Sometimes it carries off the patient in a few weeks but it usually runs a chronic course with little pyrexia. The patients have frequent evacuations containing mucus blood, pus, and amœbæ. The disease lasts for months and years with periods of constipation and of diarrhœa It may be recovered from or may terminate by exhaustion from intestinal perforation and especially in abscess of the liver This variety of dysentery shows only a slight tendency to epidemicity usually it is of a chronic character and the blood of the patients does not cause agglutination of the bacillus of dysentery Bacterial dysentery on the other hand is epidemic and infectious in a high degree. It may kill rapidly by its specific virus, but it very often becomes chronic and gives rise to ulcerations and considerable thickenings of the walls of the large intestine In addition to being epidemic it may also occur in isolated cases and may show itself as a complication in various chronic diseases It is caused by a specific bacillus multiplying in the intestinal cavity in the walls of the large intestine, in the mesenteric ganglia in the spleen and often in other parenchymatous organs the blood of patients who have been suffering from dysentery for a certain number of days causes agglutination of this bacillus. The importance of this question is evident from the fact that taking one country with another the mortality due to this disease is greater than that due to plague, yellow fever and cholera.

Successful Suture of a Bullet Wound of the Heart

Cures by suture of wounds of the heart are becoming more and more common Hitherto however all the cases reported have been of wounds caused by knife or sword but M Launay a young surgeon attached to the Paris hospitals has just related to the Academy of Medicine the details of a case in which the heart was pierced through by a revolver bullet During the operation the bullet was found lying in the pericardial cavity There were two wounds of the ventricle, one on the anterior surface and the other on the posterior surface these were sutured with catgut. The pericardium was then sutured in its turn and the flap of the thoracic wall was fastened in place No drainage was employed and the patient recovered without a single bad symptom

Death of Professor Gerhardt

DR. CARL GERHARDT professor of clinical medicine in Berlin University and chief of the second medical clinic at the Charité Hospital died on July 20th at his country house at Gamburg in Baden Professor Gerhardt was born in 1833 at Speyer in the Palatinate and received his education at Würzburg University graduating there as M D in 1856 He then became assistant successively to Professor Griesinger of Tübingen and Professor Bamberger of Würzburg In 1860 he was recognised as *privat docent* at Würzburg and in the following year he was appointed ordinary professor of clinical medicine at Jena In 1892 he returned to Würzburg to fill the chair of his former teacher Professor Bamberger and in 1885 he was appointed ordinary professor at Berlin University in succession to the late Professor Theodor von Frerichs Professor Gerhardt though not so universal a genius as the late Professor Kussmaul has done good work in several branches of clinical medicine. He was among the first to make use of the laryngoscope and he published many articles on laryngeal diseases which together with diseases of the circulatory and respiratory organs were a favourite study with him He also gave much attention to the diseases of children Not only did he lecture on this subject when professor at the comparatively small university of Jena, but in collaboration with other authors he edited a great encyclopædia on children's diseases and published a separate treatise of his own as a text-book. He also brought out works on the treatment of infectious diseases and on the history of medicine and in recent years was an active advocate of the formation of sanatoriums for phthisical patients. Professor Gerhardt was an excellent clinical teacher his delivery was clear and he possessed the faculty of making himself easily understood by junior students. His private practice was very large Last year he suffered from pneumonia, followed by permanent impairment of his health so that a few months ago he retired to his house at Gamburg where he died

New Lunatic Asylum

There are already in Berlin two municipal asylums as well as numerous private institutions of a like kind but the authorities are making arrangements to provide two additional municipal asylums one of which will be opened before the end of the present year When this intention was first announced, the authorities received a petition evidently the work of an ultra fervid abstainer asserting that the increase in mental disease was due to drunkenness and suggesting that the cost of the new institutions should be made chargeable solely on brewers, tavern keepers and others engaged in the manufacture and sale of alcoholic liquor Needless to add the petition was not even considered

Prolapse of the Rectum

Dr Karewski writing in the *Centralblatt für Chirurgie* recommends injection of paraffin in cases of prolapse of the rectum a method of treatment which, he says has proved useful after other expedients had failed The details of the operation were as follows. Purgatives were given two days previously but on the evening immediately preceding it from one to two grammes of bismuth were administered. The prolapsed part was then gradually replaced and retained in position by a finger introduced into the rectum The nozzle of a syringe was then inserted between the skin and mucous membrane and injections of paraffin were given forming a circle round the anus the paraffin on solidifying acted as a support to the bowel and prolapse did not recur Bismuth continued to be given during the next 24 hours in order to prevent premature action of the bowels With eight children treated in this way there was only one failure the other patients have remained well for periods varying from two to six months A repetition of the injection was required in two cases and two repetitions were required in one case there were no undesirable complications The operation has not yet been performed on an adult A special pattern of syringe has been made for the giving of the injection

German Practitioners' Association

The German Practitioners' Association lately held a meeting ([illegible]) at Königsberg in East Prussia. In addition to debates on all matters in the association's by-laws rendered necessary in consequence of recent legislation the meeting discussed some questions relating to sick clubs and to unqualified practice. A resolution was adopted to the effect that legislation was required making the "free choice' system[1] compulsory for sick clubs The association also expressed the opinion (1) that members suffering from venereal diseases should not be excluded from medical aid under the rules of the clubs, and (2) that persons having an annual income of more than 2000 marks (£100) should not be admitted to an official sick club With respect to unqualified practice the association adopted resolutions to the effect that puffing advertisements by such practitioners ought to be prohibited and that instructions should be given to the licensed pharmaceutical chemists (*apotheker*) not to accept their prescriptions Königsberg is in a somewhat outlying position geographically but the meeting was nevertheless very well attended. There was, however, a general complaint that the association has lost a good deal of its former importance and that the entertainments provided by the hospitality of the residents absorbed an appreciable amount of energy which ought to have been reserved for the proper business of the meeting

ROME

(FROM OUR OWN CORRESPONDENT)

Cholera Shadows

THE Italian Home Office, in view of the appearance of cholera in Egypt, although the Egyptian seaports are still untouched by the malady, has taken the following steps in the interest of Italian hygiene 1 It has established through the Italian consul in Alexandria and the Italian Legation at Cairo a daily service of information by telegraph as to the number of deaths from cholera and of cases of the disease in all the infected localities, as to the prophylactic measures, local and general, adopted, and as to the movement of Italian subjects fleeing the country 2. It imposes on ships hailing from Egyptian, and touching at Italian, seaports a special surveillance so as to ensure the practice of those precautionary measures established by the International Council of Quarantine for preventing the transmission of cholera to Europe 3 The Italian consuls at Alexandria and Port Said have instructions to telegraph to the Home Office information as to which of the said ships on the point of departure present hygienic conditions of a suspicious character, whether there are physicians on board, or the means of disinfection, whether the drinking-water is deficient or of bad quality, and whether there is excessive crowding of third class passengers 4 An order has further been issued enforcing, in terms of the "Sanità Marittima," the medical visit and inspection of ships from Egyptian ports, such visit and inspection to be made exclusively at Genoa, Leghorn, Naples, Brindisi, and Venice for the mainland, and at Palermo, Messina, and Catania for Sicily By the same order, after the said ships have been allowed *libera pratica* (free course), all who disembark from them, whether passengers or crew, will have through the local prefect to be announced by telegraph to the syndics of the communes they are bound for, so that they may be subjected to sanitary surveillance for the period required to complete the five full days calculated from the date of their leaving the last Egyptian port. Such surveillance, however, will in no case take the form of isolation and sequestration, but simply that of being subjected to the daily medical visit, followed by a certificate, when the individual leaves before the five days have expired, as to his hygienic condition, so that the syndic of the commune he is bound for may continue the surveillance up to the expiry of the said five days Finally, all prefects in maritime provinces are instructed to enforce the rigorous application of the prescribed sanitary regulations, particularly as to the medical visits and disinfections

The Suicidal Fever

From July 14th to 26 h—a statistical period of 14 days—no fewer than 23 suicides, effective or abortive, hav been announced on the part of individuals residing in, o hailing from, Rome Of these victims of real or intende self murder the great majority are females—generally girl of the poorer class who have been abandoned by husband o lover after marriage or seduction. The mode of death the affect is generally poison—a handful of lucifers dissolved i water or pastilles of corrosive sublimate Out of 15 suicide four only were above 25 years of age six above 2 three above 15, and two above 14 It is almost exclusively the male sex in Italy who destroy themselves with the knife, razor or revolver That suicide is contagious has often been maintained and proved in THE LANCET and the question arises how far the newspapers are justified in recording such cases, or at least in publishing the full circumstances in which the fatal purpose has been provoked or the particular mode in which it has been effected In the British press the intimation of a suicide is (in most instances) overshadowed by the preponderating interest of current affairs, imperial and domestic, and attracts but small attention. In Italy, however, where such interests are confined to a few, suicide (like homicide or highway robbery or theft on a grand scale) forms the chief attraction of the newspaper, which naturally seeks to gratify the morbid appetite which craves for such pabulum. When Italy develops a healthier civic life, with its concomitants of greater prosperity and higher scale of living—above all when she is better instructed and better educated—"miseria" will have decreased, sensational literature will find a smaller public, and, naturally enough, suicide will have fewer provocatives, whether in ill regulated emotion or by the contagion of example

Honours to Dr Baccelli

On July 30th, at the Ministry of Agriculture, of which Dr Baccelli holds the portfolio, with a seat in the Cabinet, Prince Felix Borghese headed a deputation to present him with a sumptuous gift, taking the form of a shield, artistically designed and ornamented, in token of the gratitude of the agricultural interest for his Excellency's discovery of the cure for aphtha epizootica and the admirable results that have attended its practice Dr Baccelli thanked the donors in a short speech of characteristic geniality and skill.

Degrees of Bachelor of Medicine and Master in Surgery.—Martha Georgina Isabella Cadell, Scotland; Leslie Alexander Drake, England; Robert James Irving, B.Sc., England; James Henry Paterson, Scotland; and Alexander Robertson, Scotland.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—May Agnew, Ireland; Robert George Archibald, India; James Arthur, England; Alexander Kidd Baxter, Scotland; Nina Henrietta Beath, Scotland; Constance Agnes Bennet, Scotland; Breadalbane Blacklock, Scotland; William Blackwood, Scotland; Garth Swinnerton Blandy, England; §Christian Henry Bösenberg, South Africa; Johannes Roos Bosman, South Africa; Edward Arthur Braine, M.A., England; George Bell Brand, Scotland; John Grant Briggs, England; Robert Dods Brown, Scotland; Herbert Henry Bullmore, Australia; Duncan Macnab Callender, M.A., Scotland; Ewen Cameron, England; §Charles Macfie Campbell, M.A., B.Sc., Scotland; George Savery Carey, England; Donald Gordon Carmichael, Scotland; James Charles Gordon Carmichael, Scotland; ‖Thomas Francis Cavanagh, Ireland; Austin Mack Caverhill, Scotland; Archibald Francis Reignier Conder, Scotland; James Harris Connolly, Ireland; §Paula Theodora Copeland, Scotland; Alexander Peter Cosker, South Africa; Harry Lovett Cumming, Scotland; Maurice Davies, Wales; Frank Inglis Dawson, Scotland; Margaret Scott Dickson, Scotland; ‖Jan Dommisse, Cape Colony; Cecil Bolton Drew, South Africa; Henry John Dunbar, Scotland; James Ferguson Duncan, New Zealand; John Duncan, Scotland; §Sören Anton Ellerbek, Denmark; James Sands Elliott, New Zealand; Samuel Charles Ellison, Ireland; John Fairbairn, British Guiana; Alfred Nolan Fell, New Zealand; Duncan Campbell Lloyd Fitzwilliams, Wales; Andrew Binny Flett, Scotland; Agnes Josephine Gardner, Scotland; §Sidney Gilford, England; Archibald Gillespie, Scotland; Edward Carwardine Gimson, England; ‖Dwarka Prasad Goil, India; Thomas Gowans, England; Mabel Dalton Gulland, Scotland; John Frederic Haggert, India; §Thomas Bogie Hamilton, Scotland; Dirk Jacob Hamman, South Africa; Alexander William Montgomery Harvey, Scotland; Alexander Walker Hauman, Cape Colony; Mathew Holmes, Scotland; Cecil Hobart Houghton, Ireland; William Hume, Australia; John Hunter, Scotland; Richard Charles Irvine, Tasmania; Miles Johnston, Uruguay; Harold Karr, Scotland; Robert Donald Kidd, Natal; James Kirkwood, Scotland; Hubert Astley Knight, England; Wilfred Elwyne Knight, Ireland; Hermann Kramer, South Africa; William Landsborough, Scotland; George Ivanhoe Lecesne, Jamaica; §Norah Lenwood, England; ‖William Lillico, Ireland; Andrew Walker Bulst London, Scotland; ‖Robert Cranston Low, Scotland; John Glenn M'Caughey, Ireland; William Fraser MacDonald, Scotland; Wilfrid M'Farlane, Scotland; ‖David Robertson MacGregor, B.Sc., Scotland; Neil Fletcher MacHardy, Scotland; Isabel Nivison M'Keand, Scotland; Samuel Walker Maclean, Ireland; Fran Macmillan, Scotland; Robert Patrick M'Neil, Scotland; George M'Neill, Scotland; William Edward Marshall, Scotland; John Kennedy Matheson, Scotland; ‖Paul Mathews, England; Robert John Mayberry, Ireland; Edmond Langley Meynell, England; William Stuart Milne, India; Richard Caldecott Monnington, England; John Howard Montgomery, Ireland; Stuart Alexander Moore, B.A., New Zealand; John Morrison, Ireland; Philip Henry Mules, New Zealand; Ronald Stuart Munro, England; Donald Norman Watson Murray, New Zealand; Charles Nelson, Scotland; William Newlands, New Zealand; Frank O'Neill, Ireland; ‖Thomas Henry Osler, South Africa; Harry Overy, England; Sophie Palmer, England; Anthony Scott Parker, England; James Hunter Harvey Pirie, B.Sc., Scotland; John Politschl, England; Edward John Porteous, Scotland; William Guthrie Porter, B.Sc., Scotland; Ivan Christopher Prichard, Wales; Agnes Melville Pringle, Scotland; Andrew Francis Honeyman Rabagliati, England; Jan Abraham Raubenheimer, Cape Colony; John Joseph Redhead, Venezuela; Antonio Baptista dos Remedios, Portuguese India; Henry Howard Roberts, England; James Stewart Eadie Robertson, England; Andrew Beaconsfield Ross, M.A., Scotland; ‖Thomas William Elmonston Ross, Scotland; Andrew James Rowan, Cape Colony; David Sandler, Russia; ‖James Scott Sewell, England; Alexander M'Gregor Sharp, M.A., Scotland; Charles John Shaw, Scotland; George Duncan Sloan, England; Morton Warrack Smart, Scotland; William Francis Smeall, Scotland; James Martin Smith, Scotland; Henry Martyn Stumbles, England; David Sutherland, Scotland; Herbert Pank Thompson, England; Alexander Dutchart MacArthur Thomson, Scotland; George Clark Trotter, Scotland; Philip Vickers, Jamaica; John Frederick van de Sandt de Villiers, South Africa; §Benjamin Philip Watson, Scotland; ‖Allan George Waugh, Scotland; John Wier, Ireland; Ada Wilkinson, New Zealand; Mary Ruth Wilson, England; Samuel Alexander Kinnier Wilson, M.A., Scotland; Edward Ernest Wood, Cape Colony; and Robert Tannahill Young, M.A., Scotland.

§ Passed with first-class honours.
‖ Passed with second-class honours.

Special University Certificate in Diseases of Tropical Climates.—William Blackwood, M.B., Ch.B.; Thomas Francis Cavanagh, M.B., Ch.B.; Dugald Christie, F.R.C.P., L.R.C.S.; Joseph Eugene Horace Gentil, L.R.C.P. & S. (*in absentia*); Dwarka Prasad Goil, M.B., Ch.B.; Robert James Irving, B.Sc., M.B., C.M.; James Kirkwood, M.B., Ch.B.; Hubert Astley Knight, M.B., Ch.B.; Wilfred Elwyne Knight, M.B., Ch.B.; John Kennedy Mathieson, M.B., Ch.B.; John Hally Meikle, M.A., B.Sc., M.B., C.M.; William Stuart Milne, M.B., Ch.B.; William Newlands, M.B., Ch.B.; James Henry Paterson, M.B., C.M.; Antonio Baptista *dos Remedios*, M.B., Ch.B.; Frederick Stanley Rose, M.B., C.M.; James Scott, M.D., C.M.; and Elizabeth Thompson Selkirk, M.B., Ch.B.

The following prizes, fellowships, and scholarships have been awarded: Gunning Victoria Jubilee Prize in Practice of Physic, Frederick Gardiner, B.Sc., M.D., C.M.; Ettles Scholarship, Benjamin Philip Watson, M.B., Ch.B.; Allan Fellowship in Clinical Medicine and Clinical Surgery, Thomas Henry Osler, M.B., Ch.B.; Freeland Barbour Fellowship, David Robertson MacGregor, B.Sc., M.B., Ch.B.; Buchanan Scholarship in Gynæcology, Benjamin Philip Watson, M.B., Ch.B.; James Scott Scholarship in Midwifery, Robert Cranston Low, M.B., Ch.B.; Mouat Scholarship in Practice of Physic, Christian Henry Bösenberg, M.B., Ch.B.; Stark Scholarship in Clinical Medicine, Thomas Bogie Hamilton, M.B., Ch.B.; M'Cosh Graduates and Medical Bursaries, Charles Macfie Campbell, M.A., B.Sc., M.B., Ch.B.; Beaney Prize in Anatomy and Surgery, Sidney Gilford, M.B., Ch.B.; Pattison Prize in Clinical Surgery, Philip Anthony Harry; Dorothy Gilfillan Memorial Prize, Paula Theodora Copeland, M.B., Ch.B.; and Cameron Prize in Therapeutics, Major Ronald Ross, I.M.S., C.B., F.R.C.S., F.R.S., for his researches on the transmission of malaria by mosquitoes, &c.

The following is the official list of passes at the recent first, second, and third professional examinations in the Faculty of Medicine.

First Professional Examination.—J. H. Aikman, M.A.; J. A. Ainscow; A. G. Anderson, M.A., B.Sc.; D. W. Anderson; W. H. Armistead; Alfred Arthur; R. C. E. Atkinson, M.A.; Aung Tun, B.A.; C. F. Bainbridge; D. M. Barcroft; H. W. Binks; E. J. Black; Frank Blamire; J. D. Bowie; H. F. Briggs; Mary Brown; H. C. Buckley; D. S. Bulst; Edward Burnet, B.A.; A. L. Chisholm; William Core, M.A.; I. H. Cornelius; S. G. Corner, M.A.; R. S. Cotter; R. C. Cunningham; J. A. Currell; J. S. Daniell; A. D. Darling; Jagonmohon Dass; Richard Davidson; Arnold Davies; A. J. Davin; J. T. Dickson; J. D. C. Duncan; D. D. Dunn; David Eakin; J. S. Edwards; V. L. Evans; H. F. Fenton; J. G. Fleming; Robert Fraser; J. W. Frew; Michael Garin; E. C. Girling; J. F. Gordon; W. L. Gordon; W. H. Gowans; *G. A. Grierson; *E. R. Grieveson, B.A.; C. M. Hall; William Henderson; W. [illegible]
O Johnston [illegible]
Jones, J. H. [illegible]
N. P. Lloyd [illegible]
Peter M'Derm[illegible]
M'Gowan, G. [illegible]
J. N. MacLau[illegible]
MacPhail; K. W. D. Macrae; Paula Maier; J. S. Manson; C. Irvine Milne; C. James Milne; J. R. Mundon; H. J. Moro, M.A.; John Morrison; Meher A. D. Vacrafi; Joseph Newall; H. S. Nicolson; J. L. H. Paterson; J. S. Preblee; George Pollock; C. E. Powell; Austin Priestman; Claude Pycroft; Edith G. Pycroft; W. C. Riley; John Ritchie; W. A. Robertson; M. J. Da Rocha; Alastair Ross; Z. M. H. Ross; A. C. Russell; Eustace Russell; W. O. Sclater; S. C. Sen; J. O. Shircore; Archibald Simpson; E. D. Simson; D. M. Smith; Harold Smith; R. S. Steuart; Harry Stokes; W. J. P. Sutherland; D. R. Taylor, B.A.; J. A. Taylor; E. R. Thompson; H. H. Thorburn; J. N. Turnbull; L. W. Vaughan; A. G. Visser; G. F. C. Wallis; Martha B. Webb; H. C. Weber; W. O. Whiteley; F. P. Wernicke; W. O. Whiteside; C. H. Williams; C. R. Wills; E. D. Wilmot; Emily C. Wybourne; and *A. W. Young.

Second Professional Examination.—Mark A. Akenzie; Francl Baillie; D. W. Boswell; F. S. Brennan; Mary T. Cameron; T. F. Campbell; D. M. C. Church; M. L. Cohen; A. G. Cook; G. M. Coughtrey; T. E. Coulson; J. G. Craig; Robert Donaldson, M.A.; G. T. Drummond; C. G. Edmondston; P. J. Elliot; C. L. Eyles; J. J. M. Falconer; G. H. L. Fitzwilliams; W. H. Forsyth; R. F. Gaskell; David Golding; Eleanor A. Gorrie; C. Ross Greenfield; E. J. Griffiths; J. H. Hume; Annie Jackson; John Jardine; G. P. Joy; Fair Jung; C. A. Lawrence; A. G. Leitch; S. M. Livesey; A. P. G. Lorimer; D. H. C. MacArthur; William M'Conaghy; James Mackenzie Inverues; Alexander MacRae, M.A.; M. M. Mamourian; J. A. Mathers; G. D. Mathewson; H. P. Milligan; C. I. S. Mitchell; Venancio Moralejo; John Morri; A. W. Neill; Armand Pantpellonne; W. J. Paterson; Bernard Pickering; A. O. P. Reynolds; Joseph Robinson, B.Sc.; John Saffley; J. G. B. Shand; J. I. Shepherd; R. H. Smith; Alexander Stephen, M.A.; F. H. Stewart, M.A.; George Stewart; R. J. Stewart; J. R. Tannahill; R. S. Trover Todd, M.A.; T. S. Vathan; Helen R. Vickers; R. R. Watt; J. D. Wells; W. F. J. Whitley; G. H. Winch; and Thomas Wright.

Third Professional Examination.—Farhat Ali, B.A.; John Allan; G. C. Anderson; F. H. Borthwick; J. C. Boyd; W. F. Brayne, B.A.; G. G. Cumming; Sam Cunliff; G. A. Davies; J. R. Dodd; In C. E. Dumanoire; H. J. George; H. W. Gough; T. M. Guthrie; Philip Hallam; L. C. V. Hardwicke; J. O. Heyn; R. D. Hole; S. A. Johnston; Saldorsafar Khan; F. F. Larkins; F. W. Lundie; J. W. M'Ewan; G. S. Mackay; William [illegible]
W. C. Morton, M.A.; Ernest Mc[illegible]
O'Flaherty; T. G. E. Parry; La[illegible]
C. F. T. Scott; Henry Speirs; D. T[illegible]
Toit; Louis Turlansky; Candfore [illegible]
Webster; D. H. Wessel; George Wi[illegible] and W. J. We[illegible]

With distinction.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND THE FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the July meeting of the

Scottish Conjoint Examining Board held in Glasgow the following candidates passed the respective examinations —

First Examination —William Hanna Clarke Gavin Watson Hill James Logan James Beveridge Macgregor and John Moncrieff Muir, Anderson s College Medical School William Robert Ellis John Henry Morris Jones and John M Arthur (with distinction), St Mungo s College Glasgow and Ernest Albert Hartland and Henry Ruddock Morehead Queen s College Cork

Second Examination (five years course) —Robert Crothers Queen s College Belfast Ernest Albert Hartland Queen s College Cork William M Ilraith William Noble Walker and John Watt Anderson s College and John Roberts and John Hughes Roberts St. Mungo s College

Second Examination (four years course) —Gilbert Elliot Aitken and Frank Hendry Rae Edinburgh School

Third Examination —Mary Lucinda Calderwood Edinburgh School Katherine Mary Chapman Queen Margaret College Glasgow Ian Campbell James Robert Robertson and James Booth Paterson of St Mungo s College William Arthur Magill Queen s College Belfast Samuel Robert Scott Queen s College Belfast and St Mungo s College Cecil James Todd Durham University School Newcastle-on Tyne.

Final Examination (and admitted licentiate of the three co-operating authorities) James Charles Galloway Henry Rayner Helsby, Thomas Joseph M Kaigney Joseph Edward Mullan Robert John Roberts Peter Carruthers Watt David Roberts Williams and Andrew Young St Mungo s College Michael David Ahern Queen s College Cork Henry Doig (with distinction) John William Dougall and Alfred Hardman Mountcastle Anderson s College Richard Hewson Hunter Glasgow University and Anderson s College James Cullen Edinburgh University and Anderson s College Richard Lewis, University College Liverpool and St Mungo s College Joseph Caton Shelmerdine Glasgow University Dora Elizabeth Lockwood and Constance Muriel Scott London School of Medicine for Women Raghunath Vithal Khedkar Grant Medical College Bombay William Anderson William Boyd Queen s College Belfast and the Edinburgh School Hamilton Marie Watson Surgeon s Hall Edinburgh Albert Edward Griffith Catholic University School Dublin and David Christie Grant Medical College Bombay and St. Mungo s College

A COMPLAINT AGAINST A PUBLIC VACCINATOR — At a meeting of the Kingsbridge (Devon) board of guardians held on July 26th, a discussion took place with regard to the charges made against one of the public vaccinators of altering the ages of the children entered as vaccinated in his vaccination register, and thereby becoming entitled to extra fees Reference has already been made to the subject in THE LANCET of July 12th, p 119 The Local Government Board now stated that the explanation given by the public vaccinator did not appear to be satisfactory, and the guardians unanimously resolved to call upon him to resign his position of district medical officer and public vaccinator

THE DEATH OF MR. P H SECKER —The tragic death of Mr P H Secker calls attention to the latent powers of danger in the compounding of even well known drugs It appears that Mr Secker, a well known veterinary surgeon of Boroughbridge, was engaged in the preparation of some horse powders containing as their chief constituents sulphur, chlorate of potash, and iron. From the evidence given at the inquest it would seem that these substances were being ground together in a mortar when a terrific explosion ensued which wrecked the room and resulted in the death of Mr Secker The cause of the explosion does no apparently need much investigation. Sulphur is ready enough to combine with oxygen, and chlorate of potash rich in this element, provides the means for the sudden detonation which concussion in the mortar would bring about To prevent a repetition of such an accident it is essential to remember that with mixtures of this character the ingredients should be ground separately and afterwards mixed, the mixture being effected with as little friction as possible

LITERARY INTELLIGENCE — Messrs W B Saunders and Co 9, Henrietta street, Covent garden, announce for early publication a new treatise on diseases of the skin by Henry W Stelwagon clinical professor of dermatology in Jefferson Medical College and Women's Medical College, Philadelphia. The work will contain a large number of half tone and coloured plates, with 1115 pages of text. A new volume in their Medical Hand Atlas series will also appear shortly, entitled "Abdominal Hernias," by Dr George Sultan of Göttingen, edited, with additions by William B Coley, M D, clinical lecturer on surgery, Columbia University (College of Physicians and Surgeons), New York, and will comprise 277 pages of text with 119 illustrations, 36 of them in colour —Messrs J & A. Churchill announce that an important change is to be made in the 1903 issue of the Medical Directory Year by year the volume has, owing to the growth in numbers of the medical profession, become more and more bulky and the proportions of the book are to be altered by increasing the size of the page, thereby reducing the thickness of the book. In 1845 the volume was issued in post 12mo size, in 1861 it was enlarged to demy 8vo, in 1903 it will be published in royal 8vo (9¾ by 6⅛ inches) The change will, it is hoped, result in a much handier and more attractive looking book.

INSTITUTE OF CHEMISTRY —According to the pass list just issued by the council of the Institute of Chemistry of Great Britain and Ireland, in the intermediate examination for the Associateship 24 candidates presented themselves and 12 passed, in the Final Examination 25 candidates presented themselves and 12 passed. This is a somewhat high proportion of failures which would appear to be due to the inefficient training of the candidates who failed, the standard of examination remaining the same

PRESENTATION TO A MEDICAL MAN —On Friday evening August 1st, at the patients weekly dance, Mr A. Rigden, who has been acting superintendent of the County Asylum, Bicton Heath near Shewsbury, for the past four months, was the recipient of a liqueur stand, which was presented by the nurses male attendants, and members of the staff as a token of their esteem and as an indication of the pleasant memories which they associated with his tenure of office

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN —The annual general meeting of this society was held at the Hotel Cecil, London, on July 16th, Dr Henry Ashby of Manchester, presiding The following gentlemen were elected office bearers for the ensuing session —Council Dr Henry Ashby Dr Fletcher Beach, Mr Herbert L Carre Smith, Dr Edmund Cautley, Dr Wayland C Chaffey, Mr Clinton T Dent, Mr Walter Edmunds, Dr Leonard G Guthrie, Dr Robert Hutchison, Mr Francis Jaffrey, Mr T Sinclair Kirk, Dr David B Lees, Dr Charles J Macalister, Dr Lewis Marshall, Dr Robert G McKerron, Mr Henry Betham Robinson, Dr A Ernest Sansom, Dr George E Shuttleworth, Mr Harold J Stiles, Dr George A Sutherland, Dr James Taylor, Mr Alfred H. Tubby, Mr Richard H. A. Whitelocke and Dr William A. Wills Honorary Treasurer Mr R. Clement Lucas Honorary Secretaries Mr Sydney Stephenson, Dr George Carpenter, and Dr Theodore Fisher After the meeting the members and their friends, to the number of 80, dined together The honorary treasurer of the society, Mr R Clement Lucas, announced that Mr C Wightman, chairman of the Evelina Hospital, had generously placed the sum of £20 per annum at the disposal of the council for the purpose of furthering original work in children's diseases A feature of the gathering, it may be noted, was the number of hospital governors present

LEICESTER INFIRMARY —The new surgical wing of Leicester Infirmary was formally opened by Mrs T Fielding Johnson on July 24th in presence of a numerous company The accommodation thus provided consists of two operation theatres, anæsthetic room, a number of rooms and offices for the use of various officials and members of the medical staff, and a complete suite of rooms for casualty, surgical, and emergency cases, the basement contains the dispensary stores, laboratory, and heating and ventilating appliances All the floors are either mosaic, marble terrazzo, or teak. The walls of the surgery, waiting hall, nurses' rooms, anæsthetic room, and corridors adjoining the theatres are tiled and have rounded angles The whole of the remaining walls, excepting those of the theatres, are finished with Parian cement The operation theatre walls are faced seven feet high with white veined statuary marble, having a dove-coloured marble border at the top and bottom The theatres are each of them lighted from the north. The artificial lighting will be by electricity The heating is partly by steam and partly by hot water coils The operation theatres, nurses' sterilising and workroom, anæsthetic room, and emergency ward are all heated and ventilated by the "plenum" system The cost was £12,000 and has been defrayed by a fund raised by the late Alderman Lennard in connexion with a scheme for commemorating the reign of her late Majesty Queen Victoria. The new buildings have therefore received the name of the Queen Victoria Memorial Wing After the ceremony the Mayor and Mayoress entertained a large company at a garden party in the grounds of the infirmary On July 25th the Mayor (Alderman E. Wood) gave a dinner in the Museum Buildings to the honorary medical staff of the infirmary and the medical profession of the town. The Mayor proposed the toast of "The Medical Profession" in a very complimentary speech which was replied to by Dr C H. Marriott and Dr F M Pope.

DONATIONS AND BEQUESTS —The treasurers of the Middlesex Hospital have received from an anonymous donor per Mr A. Pearce Gould, the sum of £100 to the fund of developing the work of the cancer research department of that hospital.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN —At a meeting of the council of the Pharmaceutical Society of Great Britain held at 17 Bloomsbury square on August 6th, Dr William Palmer Wynne, F R S assistant professor of chemistry in the Royal College of Science, South Kensington was appointed to the Chair of Chemistry in the School of Pharmacy of the Pharmaceutical Society of Great Britain in succession to Dr J Norman Collie, F R.S. who was recently appointed to the Chair of Organic Chemistry in University College London.

BOARDS OF GUARDIANS AND VACCINATION —At a meeting of the St. Germans (Cornwall) board of guardians held on July 31st a letter was read which had been received from the Local Government Board in answer to certain questions asked by the guardians As mentioned in THE LANCET of July 12th, p. 119 the guardians had inquired whether the public vaccinator might accept fees which the individuals vaccinated offered to pay him and also whether the public vaccinator had power to insist upon persons going to his surgery for revaccination purposes The Local Government Board stated that there was nothing to prevent a public vaccinator performing in his private capacity vaccination or revaccination on persons at their own expense, but in such cases the lymph supplied by the Board must not be used The Local Government Board also said that no action on the part of the guardians would be regarded as proper that would have the effect of suggesting to the public that vaccination and revaccination were not free to all residents irrespectively of social position. In conclusion, the communication added that the public vaccinator was to attend at the homes of persons for the purposes of revaccination if so requested or if not so requested the operation could be performed at his surgery or at such other place as might be arranged by him with the person so applying A considerable discussion took place on the matter and it was considered that the communication would be of interest to many boards of guardians the chairman remarking that it was plain that the Government encouraged vaccination to the greatest possible extent, that it was to be conducted quite irrespectively of social station, and that boards of guardians could not take any action against persons who did not pay for the operation.—At a meeting of the Torrington board of guardians held on July 26th a discussion arose relative to a communication which had been received from the conference of the metropolitan boards of guardians urging the reduction of the vaccination fees The chairman said that the public vaccinator in many cases received a penny a mile for his journey and if he went over five miles to vaccinate a child he received 2s 6d which certainly could not be regarded as very much. One of the guardians said that the Vaccination Act was a bad one as vaccination used to cost the union about £24 per annum whereas it was now about £70 per annum. The board eventually decided to take no action in the matter

Parliamentary Intelligence

NOTES ON CURRENT TOPICS

Midwives Bill.

THE Midwives Bill received the Royal Assent by Commission on Thursday July 31st.

HOUSE OF COMMONS.

WEDNESDAY JULY 30TH

Vaccination Prosecutions

Mr GEORGE WHITE asked the Home Secretary whether his attention had been called to the case of Sydney Ed. Pratt who on Monday July 21st was prosecuted before the bench at Grimston Norfolk, for failing to have his child vaccinated and fined 10s and 12s 6d costs though he had on two occasions appeared before the same bench asking for a certificate of exemption on conscientious grounds; and would he say whether he was prepared to promote legislation to deal with such cases.—Mr RITCHIE replied: If as would appear from the question the defendant had not established his claim to a certificate of exemption it is not clear on what grounds it can be suggested that the conviction was wrong or that any action on my part is called for

Equipment of Military Hospitals in India

Mr WEIR asked the Secretary of State for India whether arrangements had yet been made to withdraw from the military hospitals in India surgical instruments fitted with wooden handles and to supersede them by instruments with metal handles and of modern type —Lord GEORGE HAMILTON replied The whole question of the provision of aseptic instruments and appliances for military hospitals in India is now under the consideration of the Government of India The steps to be taken in the matter will be reported as soon as possible.

Sale of Opium in Burma

Mr HENRY J WILSON asked the Secretary of State for India whether he could lay upon the table the draft of the new opium scheme for Burma, of which particulars had appeared in India and which had been under consideration for some time past; also what means were being taken to ascertain Burman opinion on the new scheme and whether it was calculated to lessen the evils produced by opium consumption in Burma, as set forth by Chief Commissioners Sir Charles N Aitchison and Sir Alexander Mackenzie —Lord GEORGE HAMILTON replied: I have not as yet received a copy of the regulations for giving effect to the revised arrangements for the licensed sale of opium in Burma which I have sanctioned with the object of suppressing smuggling and checking illicit consumption These arrangements were the result of careful and prolonged inquiries on the part of the Government of Burma and I have every reason to think that due account was taken of the wishes and habits of the people

THURSDAY JULY 31ST

Lead Poisoning in the Pottery Trade

Sir CHARLES DILKE asked the Home Secretary if he would state whether the scheme of workmen's compensation in cases of lead poisoning communicated by the employers to the workers was a complete scheme intended to fulfil the promises made during the recent arbitration on the special rules or if there were other portions of the scheme not made public; and would he state if the scheme extended to the whole pottery trade in all parts of the United Kingdom.—Mr RITCHIE replied: I do not know what statement with regard to the scheme has been made public. I have received copies of the memorandum and articles of association of the company which pottery manufacturers have formed in connexion with the scheme and of its rules and regulations. These documents appear to me to contain a complete scheme for compensation to workpeople in potteries who may be suspended from work on account of lead poisoning The scheme is of course voluntary on the part of the manufacturers and there is no power to make it compulsory But it is open to all pottery manufacturers to join and more than 100 firms, including nearly all the leading potters in North Staffordshire have already become members I think that the best results may be expected from the action which the manufacturers have thus taken —Sir CHARLES DILKE asked the Home Secretary if he could state who tested for the Home Office samples of glaze when application was made by manufacturers of china and earthenware for various exemptions from certain of the special rules; how many such samples had been tested since the new special rules came into force and what arrangements were made for testing samples taken from time to time from firms working under such exemptions.—Mr RITCHIE said: The present arrangement is that samples of glaze, whether formally submitted by manuf cturers [illegible]
Government Laboratory [illegible]
of lead So far there are [illegible]
depen l on the question o [illegible]
the latest from July 25th [illegible]
the 5 per cent standard of lead and 1 to the 2 per cent. standard Few samples have yet been taken but the Inspectors will have instructions to take them from time to time in such a way as to test the observance of the rules

Pure Water for Soldiers on Active Service.

Sir MICHAEL FOSTER asked the Secretary of State for War whether with a view of preventing the danger arising from enteric fever or other water-borne diseases in war he would consider the advisability of establishing on a permanent basis some such scheme as that which was under favourable consideration in respect to the late war in South Africa, by which the soldier in the field was to be provided with approved or safe water or other liquids.—Mr BRODRICK replied Experiments will be made on the first opportunity with improved watercart designed to bringing clarified water to places appointed for its sterilisation Different methods of sterilising water by heat filtration, or chemical means are under consideration The scheme has not yet been sufficiently tested to justify its establishment on a permanent basis.

[illegible] I am awaiting an answer f om the [illegible] I addressed to them on th subject in [illegible] tably elapse before they will be in a position to reply

Poor-law Medical Officers in Ireland and their Holidays

This question was discussed in connexion with the Committee stage of the Local Government (Ireland) No 2 Bill. On the motion of Mr

Wyndham an amendment was made in Clause 3 of the Bill providing that the salary paid to a substitute during the vacation of a medical officer shall not establish any claim for compensation.—Mr Tully moved an amendment to provide that the Government contribution to the salary of a substitute shall be paid not only when the medical officer is on holiday but also when he is absent through sickness or other circumstances beyond his control —Mr Wyndham opposed this amendment holding that the proposed expenditure o public money could not be justified —Mr Macartney supported the amendment and appealed to the Chief Secretary to accept it —Mr Wyndham said that he was sorry to seem obdurate but he would undertake to look very closely into the Local Taxation Account in the autumn and see what could be done in this connexion The amendment was pressed to a division and defeated by 122 against 86 votes

Monday August 4th

Underground Workshops in Scotland

Mr Weir asked the Home Secretary whether his attention had been called to a circular issued by the Scottish Operative Tailors and Tailoresses Association relative to the effects to health arising from employment in pit or underground workshops in Scotland and would he say what action he proposed to take in the matter —Mr Ritchie replied The honourable Member has kindly sent me a copy of the circular referred to in his question It is a paper which was apparently printed two years ago but which was not communicated either to the Home Office or to the factory inspectors Since that time the law with regard to insanitary workshops has been considerably strengthened by the Factory Act of last session and I am informed that several underground workshops in Glasgow have been closed during the last two years I am not prepared at the present time to propose any further amendment of the law but if any cases of underground workshops which cause injury to health are brought to the notice of the inspectors of factories they will do their best to deal with them under their existing powers or to put the local authorities in motion

The Royal Army Medical Corps

Dr Farquharson asked the Secretary of State for War whether the augmentation of the number of medical officers on the list of Colonels Royal Army Medical Corps notified in the War Office Gazettes of June 13th and July 22nd 1902 was the augmentation which was provided for in the Estimates passed by the House of Commons in April and May 1900 and seeing that the delay in carrying out the augmentation unfavourably affected the position of some officers on the list of Colonels Royal Army Medical Corps would he take steps to rectify the same.—Mr Brodrick replied The reply is in the negative The increase of colonels in Estimates 1900–1901 was due to the necessity for providing for two supernumerary officers The recent appointments were due to the augmentation in connexion with the Army Corps scheme

DEATH

CLEGHORN.—On June 11th, 1902, at Wanganui, New Zealand, George Cleghorn, M.D. Durh., M.R.C.S., L.S.A.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births Marriages and Deaths.

Notes, Short Comments, and Answers to Correspondents

MONEY LENDERS' CIRCULARS

ONE of our readers living in a distant county has sent us a plausible circular headed "Of Special Interest to Medical Men" and signed by Messrs. Harold and Co., of 3, Holles-street, Cavendish-square, London, W. We strongly advise all our readers against entering into correspondence with advertising money-lenders or having any dealings with them of any kind. Medical men as a class are proverbially neglectful of their financial interests—a habit of mind which is due partly to the nature of their education and early training, partly to the fact that a certain amount of gratuitous work is inseparable from medical practice, and partly to the exceptional nature of the services which they are called upon to render—exceptional because it is the needs of the patient which have to be considered first and not his ability to remunerate his adviser. It is, therefore, our duty to state that for a medical man who wishes a temporary increase of capital, or is pressed by a creditor, or is otherwise in want of money, nothing is more likely to lead to disaster than accepting the overtures of an advertising money lender. The proceedings of many of these gentry have occasioned such scandals and have been so often exposed in print that an Act of Parliament mainly for the protection of their victims was passed not long ago, but means can be found of evading some of its provisions, and onerous though the contracts entered into by borrowers may be, the judges before whom such cases come for hearing are, as a matter of principle, very unwilling to cancel or modify them. The offer made in this circular of immediate cash advances "if you or your wife are in receipt of a fixed life income," and the prospect held out of obtaining such advances at 4 per cent. per annum are mere baits for the unwary. Perhaps in some few cases the promises of the circular might be fulfilled, but to disclose family affairs to a money lender would be a most serious indiscretion, and borrowers possessed of good security could always obtain better terms from a solicitor or banker. Messrs. Harold have presumably been at their present address for something less than a year, as we do not observe the name of the firm in the London Directory for 1902.

A RECORD MEDICAL MAYOR

UNDER the heading of "Another Mayoral Record" the *Westminster Gazette* of July 31st says: "Another interesting mayoral record is that of Mr. Alderman Nicholas Watson Fairles-Humphreys, J.P., Mayor of Montgomery. He was elected alderman the year of the incorporation of the borough of Montgomery, 1885; was mayor the two years of her late Majesty's Jubilees, 1887 and 1897; was elected mayor for the sixth time in 1901 for the Coronation year. Mr. Fairles-Humphrey's grandfather, Mr. Nichola Fairles, J.P., by the way, was the originator of the lifeboat movement and chairman of the first committee." The *Westminster Gazette* should have added that Mr. Alderman Fairles-Humphreys is a retired medical practitioner who was admitted a Member of the Royal College of Surgeons of England in 1864.

DIFFICULTIES UNDER THE INFECTIOUS DISEASE (NOTIFICATION) ACT

To the Editors of THE LANCET.

SIRS,—It has recently come to my knowledge that in the metropolitan borough where I reside it is the practice of the medical officer of health to visit, without any communication whatever with the medical man in attendance, all cases of adults notified as suffering from chicken-pox, and for the sanitary inspectors to visit and to inspect the arms of patients notified as suffering from chicken-pox for the purpose of seeing if vaccination has been performed or not. I should like to hear if these proceedings are general in the metropolis and agreeable to the medical profession.

I am, Sirs, yours faithfully,

August 2nd, 1902. S. W.

POINTS UNDER THE WORKMEN'S COMPENSATION ACT

To the Editors of THE LANCET.

SIRS,—I wish to inquire about a few cases which have been under my care recently in which the Employers' Liability Act possibly has some bearing. 1. Agricultural labourer under my care for kick in abdomen by a horse. The employer disclaims all responsibility for medical fee. I furnished him with a certificate for insurance company. The patient is a member of Oddfellows club of which I am medical attendant. The case was a long and trying one ending in complete recovery. Have I any claim on the employer? 2. Agricultural labourer. Crushed foot, result of wheel of cart passing over it. This man is a private patient. Am I to charge him according to his means or is the employer responsible *for medical attendance?* 3. Now under treatment. Agricultural labourer suffering from injury to foot by crush from a wheel. I had to amputate one of the toes and remove splintered head of metatarsal. Foot otherwise wounded and contused. In this case I had to summon a friend in practice five miles off to give anaesthetics. This man is also an Oddfellow in the local club

Who is responsible for my fee? If I am to expect my fee from patient himself I shall only charge out of pocket expenses If the employer is responsible I shall charge for my work This case does not come under my duties as surgeon to the club 4 Roadmaker employed by district council suffering from internal derangement of the knee-joint from a slight twist loosening the cartilage of it This man is an Odd fellow also Who is responsible for his medical treatment? I have written inquiring about these cases as they are constantly occurring and I scarcely know my position

I am Sirs, yours faithfully

August 3rd, 1902. QUERY

*** The medical man must in all cases look to the patient for his fee unless any other person or persons may have rendered them selves liable to pay it either by undertaking to do so or otherwise Where a workman has a claim for compensation upon his employer it is for him to sue the employer obtaining from him the expenses to which he has been put for medical attendance should the employer owing to the circumstances of the case be liable to pay these In the first three cases men tioned by our correspondent the liability if any, of the employer arises apparently under the Workmen s Compensation Act which only provides for payment to injured workmen of an amount assessed in accordance with the amount of wages lost through the injury, and makes no provision for medical expenses except where death has ensued With regard to Case 1, Where a workman has given notice of an accident he shall if so required by the employer submit himself for examination by a duly qualified medical practitioner provided and paid by the employer" (Work men s Compensation Act 1897 Sched I (3)), but the statement of our correspondent is too indefinite for us to say if this has taken place in the instance described We do not see that in Cases 1 2 or 3 the Workmen s Compensation Act affects his position while the Employers Liability Act does not apparently apply to them The last named Act may apply to Case 4 in which the nature of the accident is not given If it applied its effect would be to enable the injured man to recover from his employers in respect of the expense actually incurred by him for medical attendance The question of liability in so far as it affects the patient and his club is one to be decided between the patient the club and the medical practitioner according to the terms if any arranged between them to meet such cases There are many legal works on employers liability and workmen s compensation ranging from that by Mr Minton Senhouse (published by Sweet and Maxwell Limited at 25s including both Employers Liability Act and the Workmen s Compensation Act) to smaller volumes such as that by Mr W A Willis (dealing with the Workmen s Compensation Act and published by Messrs Butterworth and Messrs Shaw and Sons at 2s 6d) and there are other more popular" guides as well Perhaps our correspondent would find one of these useful —ED L

FEES UNDER THE NOTIFICATION ACT

To the Editors of THE LANCET

SIRS —Would you kindly enlighten me through your correspondence columns in THE LANCET on the following The authorities of this city are talking of refusing to pay me my fees for the cases of enteric fever which have been admitted into this hospital They say I am not entitled to any fees and that I need not notify the cases at all as they have been notified by the medical men who sent them in Could you inform me if there is any law on the subject? They have paid me always up to the present. Thanking you in anticipation

I am Sirs yours faithfully

August 5th 1902. HOUSE SURGEON

*** The law is laid down in the Infectious Diseases Notification Act, 1889 Section 3 Clause 1 (*b*): Every medical practitioner attending on or called in to visit the patient shall forthwith on becoming aware that the patient is suffering from an infectious disease to which this Act applies send to the medical officer of health for the district a certificate House surgeon is therefore bound to certify and the local authority is also bound by Section 4, Clause 2 to pay him a fee of 1s (the cases occurring in his practice as medical officer of a parish institution) for each certificate duly sent by him in accord ance with the Act —ED L.

CADMAN S PATENT SAFETY" AIR SHAFT COVERINGS

WE have received a pamphlet descriptive of a patent covering for the air-shaft of a house drain Instead of the usual wire case it consists of a beehive-shaped iron cover which is perforated with holes The inventor Mr Cadman was led to think out his invention by seeing a bird fly out from an air-shaft. Upon investigation he found another bird sitting on a nest of eggs and the remains of several old nests It would be an interesting research to find out what effect if any, is produced upon birds by being brought up in an atmosphere of presumably sewer gas Be this as it may Mr Cadman s cover would seem to be well adapted for keeping an air shaft free. The manufacturers are Messrs Thomas Holcroft and Sons Limited Wolverhampton

HOMICIDAL MANIA IN A NURSE

AN editorial article in the July number of the *Maryland Medical Journal* comments unfavourably on the system of recording deaths and authorising funerals in the United States saying that in perhaps a majority of instances the records of death do not contain the name of any individual who either witnessed the death or had certain knowledge that it occurred at the time or in the manner certified" These remarks were suggested by the case of a professional nurse, Jane Toppan who was arrested some months ago on a charge of having killed a patient with poison The grand jury found a true bill against her for the murder of three per sons She was suspected of having killed 11 persons At her trial at Barnstable, Massachusetts last June or July she stated to Judge Bixby that she had killed during her professional career no less than 31 persons She was found to be insane and will spend the rest of her life in the Taunton (Massachusetts) Hospital for the Insane The nurse did not give a list of her victims, but no doubt was thrown upon her count of 31 In the summer of 1901 she caused the death of three people at one place Morphia was the poison she used

THE LAW FUND

TRUSTEES THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, AND THE MASTER OF THE SOCIETY OF APOTHECARIES OF LONDON

IT is proposed to hold a meeting of subscribers to this fund at an early date In the meantime it is hoped that the subscriptions will con tinue to flow into the fund as every gift to this fund is a protest against unjustifiable action being brought against members of the profession Dr Paramore, 2, Gordon square W C has received the following additional subscriptions and will gratefully acknowledge the receipt of all donations however small Cheques and postal orders should be made payable to the Law Fund and crossed 'London and County Bank London," and sent to Dr Paramore with as little delay as possible

◆

G G I —We consider that C is wrong to return to a neighbourhood to practise in juxtaposition to A seeing that he gained his introductions to the neighbourhood by acting as A s locum tenent and assistant We understand from a written statement that C does not deny that this is the manner in which he came to practise in the neigh bourhood That C was not bound by the usual bond was an over sight on the part of A which it must be unseemly for C to take advantage of With regard to B if he was definitely informed that A had no objection to his taking C into partnership there was nothing unprofessional in his opening negotiations But when later he learned that A did object very strongly it is regrettable that he did not break off those negotiations More than this we cannot say as we do not know exactly what C has told B but the matter is obviously one for arbitration

E A D —The regulations governing medical practice in America by gentlemen holding English qualifications vary in the different states Our correspondent will find full information on this subject in THE LANCET Sept 5th, p 665 Sept 12th, 1896 p 769 and Oct 3rd, p 969 under the heading of "The Legality of British Qualifications Abroad"

Dr W Raine.—Two good books on the subject are (1) Medical Nursing Notes of Lectures given to the Probationers of the London Hospital," by the late James Anderson M D F.R C P (London H K. Lewis 1894) and (2) 'Lectures on Medicine to Nurses" by Herbert Cuff, M D Lond, F R C S (London, J & A. Churchill 1896)

ERRATUM.—In the report of the case of fracture of the tibia and fibula at the Seamen s Hospital Funchal, Madeira published in THE LANCET of June 28th 1902, p. 1834 it should have been stated that the case was under the care of Dr R E S Krohn as well as under the care of Mr J Geddes Scott

FRIDAY (15th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.).

SATURDAY (16th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (11th).—KING'S COLLEGE VACATION COURSE IN BACTERIOLOGY (Department of General Pathology and Bacteriology, King's College, London, W.C.).—10.30 A.M. to 1 P.M. Demonstrator: Dr. Willson. Lecture: Tubercle, Leprosy, and Glanders. Practical Work: Tubercle.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—4.30 P.M.: Dr. H. J. Davis: Demonstration in Medical Wards.

TUESDAY (12th).—KING'S COLLEGE VACATION COURSE IN BACTERIOLOGY (Department of General Pathology and Bacteriology, King's College, London, W.C.).—10.30 A.M. to 1 P.M. Demonstrator: Dr. Willson. Lecture: Typhoid Fever. Practical Work: Typhoid Agglutination Reaction.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M.: Lecture:—Dr. H. J. Davis: Functional Heart Murmurs.

WEDNESDAY (13th).—KING'S COLLEGE VACATION COURSE IN BACTERIOLOGY (Department of General Pathology and Bacteriology, King's College, London, W.C.).—10.30 A.M. to 1 P.M. Demonstrator: Dr. Willson. Lecture: Diphtheria. Practical Work: Diphtheria.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M.: Lecture:—Dr. E. A. Saunders: Examination of Gastric Contents.

THURSDAY (14th).—KING'S COLLEGE VACATION COURSE IN BACTERIOLOGY (Department of General Pathology and Bacteriology, King's College, London, W.C.).—10.30 A.M. to 1 P.M. Demonstrator: Dr. Willson. Lecture: Suppuration and Septic Diseases. Practical Work: Pyogenic Cocci.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—4.30 P.M.: Mr. McAdam Eccles: Demonstration in Surgical Wards.

FRIDAY (15th).—KING'S COLLEGE VACATION COURSE IN BACTERIOLOGY (Department of General Pathology and Bacteriology, King's College, London, W.C.).—10.30 A.M. to 1 P.M. Demonstrator: Dr. Willson. Lecture: Pneumonia and Gonorrhœa. Practical Work: Pneumococcus and Gonococcus.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M.: Lecture:—Dr. E. A. Saunders: Examination of Gastric Contents.

SATURDAY (16th).—KING'S COLLEGE VACATION COURSE IN BACTERIOLOGY (Department of General Pathology and Bacteriology, King's College, London, W.C.).—10.30 A.M. to 1 P.M. Demonstrator: Dr. Willson. Lecture: Tetanus and Malignant Œdema. Practical Work: Tetanus.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1902, which was completed with the issue of June 28th, and the Title-page to the Volume, were given in THE LANCET of July 5th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1902 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months...	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

An Address

ON

THE MODERN TREATMENT OF PULMONARY CONSUMPTION

Delivered before the Hunterian Society of St George's Hospital on Nov 24th 1901

BY ARTHUR LATHAM, M.A., M.D OXON, M A. CANTAB,

ASSISTANT PHYSICIAN TO THE HOSPITAL; ASSISTANT PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION; VICE PRESIDENT OF THE SOCIETY

MR. PRESIDENT AND GENTLEMEN —The subject which we have to discuss to-night is of enormous importance as every one must realise who grasps the facts that at least one individual out of every 10 dies from this disease, that among the working classes the proportion of fatal cases is even higher and that in 1897 there were over 50 000 deaths from consumption in England alone. During the last century our knowledge of the pathology of the disease has made much progress. If we turn to the teaching of the great physician, Dr Robert Graves,[1] we find the following Might not tubercles have been originally fluid and might not the change they undergo be from a soft into a consolidated mass? I have seen this passage of fluid scrofulous pus into solid matter beautifully exemplified in a case of psoas abscess the neighbouring lymphatics were loaded with pus, in the lymphatic glands to which it was next carried it was much thicker in those at a greater distance it was of the consistence of curd, and when its fluid particles had been still more completely absorbed in more distant fluids it was found to be as solid as any yellow tubercle May it not happen that many of these yellow tubercles—and this is the opinion of Cruveilhier and others who have written on this subject since Laennec—at their commencement consist wholly of depositions of scrofulous pus in the tissue of the lungs?" This extract alone is sufficient to show us how very different are the views of the present time on the pathology of consumption from what passed muster 60 years ago. In addition to this improvement in our pathological knowledge there is the great probability that, owing to the wide incidence of the disease, human beings have become less susceptible to tuberculous infection and that the tubercle bacilli have at the same time followed the natural law and become less virulent. We have these two great advantages over our predecessors—more thorough knowledge, and probably a bacillus, in the great majority of cases of diminished virulence. In addition we know now that if we see the patients in the early stages of consumption we can arrest the progress of the disease with almost absolute certainty and that in many instances disease which would have been regarded 10 years ago as hopeless can be permanently arrested, whilst in nearly all cases some improvement can be produced.

If we look at the treatment of pulmonary consumption in early days we find, for example, that Pliny[2] enumerates a variety of specifics for consumption with an almost superstitious credulity After mentioning the pectoral virtues of gum ammoniac, he observes that woods affording an abundance of resinous effluvia are very beneficial to the consumptive, even more so than a voyage to Egypt, or a course of milk in the mountains." He praises the juice of plantains, and the linctus of betony with honey He says that in Achaia a wolf's liver infused in wine, the lard of a lean sow fed on vegetables and asses flesh, together with a broth, are used for curing consumption, as are the smoke of dry cow dung drawn through a reed and the tips of bullocks horns burnt and powdered and mixed with honey Goats fat in gruel or with honey and water and a little rice is recommended by many" This very respectable author further says consumption in the last stages has been cured by the fat of a mountain goat taken in milk. Others employ the lungs of a stag with straight horns, smoke dried and triturated with wine. If we turn to Paracelsus,[3] who lived in the sixteenth century we find that the diet is of the greatest consequence, and should consist of liquorice polypody, lentils, raisins, lettuces, radishes cabbages, beet and other vegetables. An ointment is prescribed for universal friction morning and evening and the powder diacoralliorum, containing crude antimony and crocus marsh is to be given in pretty large doses until the spongy froth in the urine disappears, and an ointment chiefly composed of the fat of field mice is recommended as an experiment with the same limitations. The patient is also to try the use of a bath containing a decoction of herbs with sulphur When the disease has been once cured it is said not to return.

Such treatment at the present day sounds ridiculous but is it more ridiculous than what obtains in many instances at the present time? It is not an uncommon experience to find some unfortunate workman who lives continuously in a fœtid atmosphere and eats an indifferent amount of coarse and unnutritious food taking all of the following medicines during the 24 hours —A mixture of cod liver oil with malt, to supply so it is said, the place of the fast ebbing vital oil" a mixture of gentian and sodium bicarbonate to assist the jaded appetite an other mixture to strengthen the action of the heart when the patient feels more than usually ill some form of lozenge to allay the cough during the daytime together with a new fangled antiseptic as an inhalation, and some pernicious preparation of opium to bring sleep at night. Many of these remedies are of service in themselves, but can such indiscriminate drugging be of any value to a consumptive patient? Is such treatment any less ridiculous than the whimsical mockery of medical science that I have read from Pliny and Paracelsus?

Amongst the remedies which have been vaunted as specifics *for the cure of consumption during the last 50 or 60 years* I would mention curls made of blotting paper impregnated with ammonium chloride and inserted into the nostrils, injections of sulphuretted hydrogen into the rectum repeated bleedings debilitating drugs such as antimony the grape cure, the use of the serum of goats and asses compressed air and hot air—a truly terrible record. Finally we have what is in vogue so much at the present day the use of all sorts of antiseptics the result of this in many instances being as Dr P W Latham observed in his Harveian oration, that the patient rather than the bacillus succumbs"[4] It has been asserted that each of these remedies has produced numerous cures of tuberculosis in all its stages. It seems, however that the only deduction we can draw from the records of such treatment is that pulmonary consumption must indeed be a curable affection when it withstands such treatment as I have mentioned. In the words of the late Wilson Fox[5] it is still unfortunately true, that no medicinal remedy has, as yet, been found which can be regarded as a specific for tuberculosis

During the time that all these so-called specifics have been lauded to the skies in the treatment of this disease men have not been wanting who exercised their common-sense and came to the conclusion that the essential thing was to place the patient under such conditions that his nutrition would be improved and he himself in a position to fight the disease. In 1840 George Bodington wrote an essay on the cure of pulmonary consumption on principles natural, rational and successful," in which he insisted on the importance of a generous diet and a constant supply of pure air He further said that cold is never too intense for a consumptive patient, the apartment should be kept well aired, so that it should resemble the pure air of outside pure air being used in the treatment as much as possible" This book met with much bitter and fierce opposition and eventually the disapproval of his methods became so universal that patients were driven from his sanatorium which wa the first of its kind in the world and where several years previously to the publication of his essay he had practised his principles and effected many cures. In 1855 Dr Henry MacCormac, the father of the late Sir William MacCormac, published a book on somewhat similar lines and as a result had to bear every kind of persecution to which a man in his position can be subjected. In 1861 he read before the Royal Medical and Chirurgical Society a paper on The Absolute Preventibility of Consumption," in which he advocated what are now established principles The members of the Royal Medical and Chirurgical Society refused to pass the usual vote of thanks to Dr MacCormac, because they thought that the paper was written by a monomaniac. Dr J Hughes Bennett a few years later supported Dr MacCormac, and the following is an extract from his book. "The diet must be one of a nutritious kind, consisting of a good proportion of food of sufficient quality and quantity Fresh air and good ventilation are of essential importance. Exercise is the strongest stimulus to appetite" Again in 1864 Dr P W Latham[6] advocated the necessity of a generous diet, of successful and continuous ventilation, and of regular exercise in the open air In 1871 Niemeyer[7] wrote "A patient should be placed, if possible, under influences calculated to invigorate the constitution, and extinguish the morbid tendency A proper supply of fresh air is of equal importance to a proper regulation of diet The patient must avoid smoke or dust, air that is too hot or too cold, and must avoid great efforts in running, singing, dancing, and the like. The real value of climate is that the patient must spend the day in the open air The patient must always live circumspectly and remain under the charge of an intelligent and strict physician."

[5] Diseases of the Lungs and Pleura.

We see from these extracts that many were very near the truth, but it was not until Hermann Brehmer—who started a sanatorium a few years after the paper of George Bodington appeared—Otto Walther, and others, had perfected the details of the treatment and the marvellous results which they had obtained had become known that medical men began to understand the benefit and value of this treatment. The theory on which this so-called open-air treatment is based is common sense To fight any disease you must place your patient as far as possible under ideal conditions as regards food and air and avoidance of fatigue. This is, or ought to be, a truism You have only to look at wild beasts—such as an imported tiger—which are placed under unnatural conditions, to see how rife tuberculosis becomes in animals which in their wild state are habitually free from this disease Climate, however, is not everything For instance, in the Blood Indian Reserve of the Canadian North-Western Territories,[8] in a population of about 2000 there were, excluding diseases of infancy, 127 deaths from pulmonary consumption during six years, or 23 per cent of the total rate, and that in a tribe occupying one of the finest climates of the world, at the foothills of the Rocky Mountains In fact, we have learnt that any climate will do for the sanatorium treatment of consumption, provided that the air is pure and bracing

What, then, are the principles of this sanatorium treatment? There is only one principle—viz., to try to increase the resistance of the body, so as to render the tubercle bacilli innocuous. For this purpose the essentials are (1) A continuous supply of fresh air with no unnatural changes of temperature and the avoidance of all sources of irritation from dust and the like, (2) good nourishing food in sufficient quantity to establish and to maintain the normal body-weight of the patient, (3) an absolutely regular life, so arranged that neither the lungs nor any other portion of the body is allowed to be put to any strain, and (4) graduated exercise without strain

1. With regard to the first—viz., supply of fresh air—naturally all the usual regulations for the avoidance of bacillary infection, such as the character and furniture of a room, cleansing of knives and forks, and the use of sputum flasks must be carried out The patient must always live in the fresh air and must not be exposed to any contrast of temperature such as going from a hot room into a cold one. Day and night he must be kept in an atmosphere at the temperature, practically speaking, of the outside air In this way the body is hardened and colds are avoided *There are no exacerbations of the disease and consequently the damaged tissue has time to heal* The air must be free from dust and any deleterious products, in fact, it must be pure The patient when in his room should be alone, there must be no company and his windows should be widely open

2. The amount of food which is given at efficient sanatoriums has been greatly exaggerated. It is, however, true that at certain sanatoriums over feeding is practised, and often with injurious results. The amount which should be given is a little more than the amount taken by a healthy person, but this amount must be taken whatever the condition, however debilitated the patient may be, however high the temperature, and even if a couple of hours have to be spent over a meal. It has been shown by Dr Walther that the readiest and best way of reducing the fever of advanced consumption is by increasing the amount of solid nourishment In those cases in which the patient cannot take the food he is often enabled to do so by the administration of alcohol Three[9] meals a day are taken at intervals of five hours and the food is of all kinds, but special care is taken that it is the best of its kind and that it consists largely of fatty forms It is essential that it should be well cooked and served up in as attractive a fashion as possible, well made fat-containing sauces being an important adjunct to the treatment Each patient is helped by, and eats his food under the eyes of, the physician in charge. No food or drink is allowed between meals When the patient first comes to the sanatorium he is given at each of his three meals one pint of milk and he continues to take the milk until he has regained his normal body-weight. When the proper weight has been reached the amount of milk is reduced and the patient is allowed beer or wine.

3. Every form of fatigue must be avoided and no patient is allowed to do anything which has any tendency to raise the temperature. The exercise consists of very slow walking uphill for a short distance, varying from a few yards to a mile, or in the more healthy cases to four or five miles, a prolonged rest, and then a gradual return downhill by another path. This gradual uphill exercise has two advantages, in that it is easily regulated and, secondly, because it acts as a heart tonic Patients are not allowed to walk fast or to run, if they do there is a greater rate of respiration and more strain is thrown upon the lungs, whilst the body temperature is raised. No excitement which is found to raise the temperature is allowed. For instance, few patients are allowed to play the piano, or chess, or cards, whilst patients who are kept in bed for various reasons are not permitted to see anyone except the medical attendant. This necessity of avoiding excitement is due to the effect it has upon the temperature, it is a vital part of the treatment and must be insisted upon in all but the very earliest cases, whilst at sanatoriums it is found best that all patients should be treated alike in this manner, as any relaxation in the case of particular patients tends to relax the necessary discipline and may lead to unpleasantness I have laid stress upon this point, as many recent writers have expressed strong views on the absence of amusements in sanatoriums, showing that they have entirely failed to appreciate one of the important details of the treatment.

4 Exercise is prescribed when the condition of the patient permits There are no absolute rules, in fact such rules as exist are more frequently broken than followed. The personal factor of each individual has to be carefully considered in the matter of exercise as in all questions connected with this form of treatment Exercise, in the majority of instances, may be permitted when the temperature of the rectum taken before rising in the morning has not been higher than 98° for a week The amount of exercise is so regulated that amongst other things the temperature taken after the return from a walk is not higher than 100° If the temperature is higher than 100°, or if it fail to sink to normal within 20 minutes, or if there is any symptom of exhaustion, the amount of exercise has been too great and a shorter walk is prescribed on the following day, and so on until the patient is enabled to return to his room with the temperature lower than 100° One of the few conditions for which a patient is kept in bed is when the temperature is habitually above 98° in the morning before rising A patient may be kept on his sofa chair if the temperature is not distinctly below 98 4° before rising or if the exertion of a slight walk is enough to cause a rise of temperature. This, in many instances, however, is too rigid a rule. We may find that a patient with a morning temperature of 99° and an evening temperature of 102° who fails to make any progress whilst kept at rest loses his fever and becomes in every way stronger when permitted to take gentle exercise Exercise should always be prescribed when it does no harm. We can only find out whether it is likely to lead to beneficial results or not by carefully experimenting on the individual patient.

So much for the principles. I will now describe a day at Nordrach where the treatment is carried out with excellent results. The rooms of the patient are heated with warm water pipes or by electricity, a temperature very slightly above that of the outside air being constantly maintained during the night. The patient is called at 7 o clock in the morning and the windows of his room are then closed in order that he may not catch cold whilst dressing He takes his temperature and rises at the latest at 7 30 and then has a shower bath at a temperature to suit himself On completion of his dressing he must open the windows. Breakfast, at 8 o clock consists of tea or coffee, one pint of milk, bread and butter in large amounts, jam or honey and a dish of cold meat. Directly breakfast is finished or at 8.30 the patient starts out on his morning walk, the length of which is graduated according to his condition—it may be only a few yards. He walks deliberately and slowly until he has arrived at his destination and waits there resting in the fresh air until it is time for him to start home again. At 11.45 o clock he must be in his room in which he will find the windows have been shut and he must take his temperature. In five or 10 minutes he must open his windows which must remain open until he leaves the room Between 12 and 1 o clock he must lie resting at full length on a sofa-chair At 1 o clock he leaves his room and has luncheon with his fellow patients. This is the chief meal of the day and may consist, to give an example, of one pint of milk, hot stewed tongue, asparagus, a large plateful of potatoes, hot veal more potatoes and salad, pastry and cream bread butter and coffee. The patient starts not later than 2.45 o clock on his slow afternoon walk which is the shorter walk of the day He rests as before when he arrives at his destination and slowly returns so that he reaches home at 5.30 He again takes his temperature opens the windows which have been closed by a servant shortly before his return and rests until dinner time. At 7 o clock he goes to dinner which consists of one pint of milk, bread and butter in large quantities one course of hot meat and one of cold for example hot pork and potatoes, and cold smoked *salmon. A cup of tea after dinner is optional. After dinner* the patients may spend half an hour or more in the dining room, in which the windows are kept widely open. They retire *to their own rooms by 9 o clock* and *open their windows* which have been closed shortly before they get there. They are in bed between 9 30 and 10 o clock and should take their temperature after they have rested for a quarter of a hour

[6] On the Early Symptoms of Phthisis

[7] Practical Medicine, vol. i.

[8] Osler: The Principles and Practice of Medicine

[9] In some sanatoriums four or more meals are given at shorter intervals

Smoking is allowed in the open air so long as it does not produce coughing or is not indulged in to excess it is strictly prohibited in the patient s room Patients are persuaded to avoid attempts at coughing they are taught that every cough avoided is something spared to the lung and they soon find that they can keep the cough in check.

In addition I must mention that Dr Walther or Dr Weltz, sees every patient three times a day once before breakfast, and immediately after the morning and afternoon walk, and judges from the general condition of the patient and from his temperature whether he is taking too much exercise or whether he may safely be allowed to continue the same amount or take more. Further every week each patient is weighed—a process which gives him something to look forward to and establishes a healthy rivalry Every fortnight his chest is examined and every month the sputum is tested

It is impossible in a paper of this kind to do more than sketch matters but I have said enough to show you that the chief thing is detail detail in carrying out the great principle and constant supervision by a competent and strict, although at the same time thoughtful and encouraging physician. One further point about this treatment is the feeling of hope and faith which is inspired in every patient s heart as he watches the gradual improvement of cases worse than his own. The confidence engendered in this way in the sanatorium physician has a most beneficial effect

What are the results of this treatment? In the first place men who have failed to regain their health after years of trial at various climatic resorts go to properly conducted sanatoriums and have their diseases arrested. Symptoms such as indigestion cough night sweats often disappear like magic in a few weeks, or as soon as the nutrition of the body begins to approach the normal The results gained by treatment at Goerbersdorf by Brehmer from 1876 to 1886 were as follows In stage I cured 27 8 per cent. almost cured 31 per cent in stage II cured 6 8 per cent. almost cured 14 6 per cent. and in stage III cured 4 per cent. almost cured 2 3 per cent. At Nordrach the number of patients in whom the dis[illegible] nent arrest amount to 30 per cent [illegible] whilst all but 5 per cent. obtain [illegible] Nordrach statistics are the more remarkable when you realise that most sanatoriums prefer early cases and often limit their admissions to this class, but that Dr Walther takes them in any stage and in fact, prefers the graver ones. Most patients put on from two to three pounds per week until their proper weight is established. I will give you a typical example of a case treated by Dr Walther and graphically related, of himself, by Dr R. Mander Smyth[19] who with Dr H. G Felkin, has charge of a sanatorium at Linford near Ringwood. Dr Smyth tells how he contracted consumption how rapidly extending excavation set in in the upper portions of the right lung and how he arrived at Nordrach in a prostrate and apparently dying condition My friends were sent away and I saw only the doctor and a nurse, who was enjoined never to let me talk. The windows of my room *constituting nearly the whole of one side* of it, were open night and day and a strong draught played through them breathing of the pine-clad slopes. Once a beautiful bird perched upon the window sill and whistled a few cheery notes, a heaven-sent messenger of better fortune. I was occasionally bombarded by summer hailstorms which swept up the valley and at times in the winter waked up to find an inch of snow had silently drifted upon my bed. But far more important than fresh air were the meals. Three a day—at eight one and seven—they came with pitiless regularity A plate of pork and potatoes, a leg and wing of a chicken, salad and more potatoes and to finish a large wedge of very solid pastry would constitute a typical dinner, not more indeed than a man of hearty appetite would consume, but to the feeble invalid a Gargantuan repast. Moreover *mirabile dictu* I was persuaded by the magic of the doctor's personality to eat it all. Once only did exhausted nature absolutely rebel. It was on August 7th when I had lost half a pound in weight Then came the doctor serious and impressive, and plainly told me *that if I did not* eat I should assuredly die. The *mental* stimulus was exactly what was needed and let that be the answer to those who without knowing the real man cavil at what they call the Prussian method of treating phthisis. It was to the invalid like the encouragement of the general to his men reeling from the enemy's fire. The next week, on August 12th, the temperature which had been gradually subsiding came below normal for the first time for four and a half months of illness. Coincidently I had gained nearly five pounds weight. In five weeks I gained 22 English pounds In spite of this improvement of the temperature I was still kept in bed, only sallying forth on Saturday morning to be weighed, when I was wont to compare notes with a young Dutchman who was in a similar plight, and who ultimately recovered. We must have presented a comical spectacle tottering back to our rooms each supporting himself by the wall of the corridor It was not until the temperature had been normal for 12 days (August 25th) that I was allowed to take a walk. This meant 50 yards on the flat, resting the remainder of the day The next day I increased my walk by 40 yards or so and thus, cautiously creeping farther every day with excessive care I was able in some three weeks to walk half a mile up a gentle incline *without undue fatigue.* But it was *not until* Sept 28th, or a month after I came out of the house, that I was permitted to join my comrades in the dining hall, and even then I often spent two to three hours in eating my dinner Speech was *somewhat rusty, for my isolation* from society was a matter of nearly six months Improvement at length went on rapidly I went to bed at night and woke feeling a fresh wave of vitality come over me My daily walk became a recreation and an interest, and the magnificent views of the Nordrachthal and the thousand-and-one interesting objects that nature has lavished in that valley were a never ending source of satisfaction. In October no bacilli could be found in my sputum. At the end of November I was able to climb 1500 *feet* and on Dec. 11th a walk of 14 miles involving 3000 feet of climbing over rough mountain way was accomplished. Later on came the snow and with it the fascinating delights of coasting down the snowy timber roads an amusement I had reason to regret. About the middle of January 1897 I began to feel languid and easily tired after walking the temperature was not quite so satisfactory at night, cough and expectoration increased and in February bacilli were again found in the sputum. This was what is popularly called a chill an expression as utterly misleading as it is unscientific. It was in truth a relapse, which, slight as were the symptoms, cost me five months of extra treatment. All this trouble was caused by three days of too vigorous tobogganing, and was as purely the result of mechanical strain, not of exposure, as would be the same thing in a tuberculous joint from too free exercise of it. Under the keen supervision to which I was subjected, however, the bacilli had little chance After a week's rest on a couch I again began to walk very short distances, gradually increasing as I became stronger, and my weight, which had remained stationary during the winter, began to mount up By the middle of June I was again walking 10 or 12 miles each morning and in July, 1897, exactly a year after my arrival at Nordrach, I returned to England, where I have resided ever since. My weight on leaving Germany was 13 stones 10 pounds, a gain of three stones"

---

[19] Practitioner July [illegible]

The striking effect of the treatment in this case is excellently shown by the reproductions of photographs which accompany the article. Now Dr Walther's sanatorium is not the only one though it has such a deservedly high reputation, there are many sanatoriums in England, presided over by highly skilled men and women, which are thoroughly trustworthy Anyone living in England should attempt to be cured under his own climatic conditions, the conditions in which he must eventually live, and these he finds at Nordrach and in his own country No climate within certain limits matters so long as the air is pure and bracing, no variation in the temperature of the outside air matters so long as it is not absolutely sudden. The most important thing in sanatorium treatment is the character of the man who carries it out. Many so-called sanatoriums both in England and in Europe are conducted on the basis of a hotel and do much to bring the treatment into disrepute. The first information I want about any particular sanatorium is the character of the man at the head of it and whether he has had practical and thorough teaching in the Nordrach methods The man in command must be an absolute autocrat and must be strong enough to send away those patients who do not fulfil his directions in the spirit and in the letter It is a matter of comparative indifference where the sanatorium is situated, but in my opinion it is folly for English people in whom the disease has made material progress, who are not possessed of ample means and who have to make their living at home, to go to so called health resorts abroad where they will become accustomed to climatic conditions quite unlike our own and where they have many temptations to stray from the true path of health. Whilst I am on this point I would express my emphatic disapproval of the practice of sending patients in search of health on long sea voyages in steamships unless these are especially adapted for the purpose, as the conditions obtaining here, the stuffy air under deck the great variations of temperature and the like, are wholly incompatible with consumptive treatment

How long must patients stay in a sanatorium? It is best that they should remain until all physical signs of active disease have gone, until no tubercle bacilli are found in the sputum, and until the inoculation test leads to no result. This happens on the average in from five to six months, it may in some cases take two years or even longer, whilst in selected cases of men or women who have sufficient character to carry on this treatment for themselves in all its details, two months may be sufficient to train them thoroughly and to place them in a position in which they can look after themselves When a patient leaves a sanatorium he should be told that for at least two years he must continue the treatment as far as possible that he must avoid all severe strain upon the respiratory or other organs such as bicycling and the like, and shun all places where a large number of people are gathered together, such as theatres, concert-rooms, and churches This is an essential part of the treatment. A man whose disease is fortunately arrested must remember that he is still a weak vessel and liable to further infection or relapse if he is not careful for some considerable time He must not cry "the war is over,' or he will find that tubercle bacilli, like the Boers, suddenly swoop down from their kopjes, with the result that an unfortunate incident occurs, if not absolute disaster Patients who have had their disease arrested at a sanatorium are well advised if they have their chests thoroughly examined by a medical man at least once in every three months for several years

What cases are ineligible for sanatorium treatment? Some sanatorium physicians take any class of case however severe or apparently hopeless, patients are sent away only when after repeated efforts they cannot eat or when they get the persistent diarrhœa of intestinal tuberculosis Experience has taught us, however, that in most cases where the amount of disease in both lungs is extensive no great or permanent benefit is obtained by sanatorium treatment and it is little short of cruelty to send such patients, many of whom are obviously dying, long journeys and away from their friends for a form of treatment which in the nature of things can prolong their life only for a very short time.

One word about drugs In sanatorium treatment no drugs are used in the routine treatment of the disease, but complications or symptoms such as hæmoptysis, diarrhœa, and constipation are treated on the usual lines Generally speaking, I may repeat here what I said in a lecture on the treatment of cough in consumption,[11] the principles which must guide you in giving drugs in this disease are never give drugs until all other measures have failed, and then never without considering the question whether in treating any particular symptom you are not aggravating the disease either by disturbing the digestive capacity or in some other way

Well, Mr President and Gentlemen, I have said enough—and in doing so I am afraid I have strained your patience—to convince you of the pathetic position of one who, like myself, holds these views strongly and who is constantly seeing hospital patients afflicted with consumption Week after week I see nearly 200 patients who cannot afford the conditions necessary to the successful treatment of their disease. In the majority of instances all I can do is to alleviate the symptoms and trust that, by convincing the patients of the absolute necessity there is for them to do everything in their power to improve their nutrition and general condition they will gradually overcome their disease. In a surprisingly large number—surprising in view of their surroundings—the disease is kept in check and in some cases it is arrested, but in the large majority we can do little more than watch these unfortunate people gradually become worse and die purely from want of money Take, for example, the case of a man in an advanced stage of consumption working 16 hours a day in an underground bakery in an overheated atmosphere, with six children to support and unable to change his occupation, or that of a billiard marker in a public-house, always in a smoky and fœtid atmosphere and exposed to constant temptations, what can be done for such cases? Our only answer under present conditions is, "Practically nothing" This, gentlemen, is a national disgrace and in this way the nation is losing every year thousands of lives and large sums of money The only effectual remedy is, as Sir John Burdon Sanderson[12] has pointed out, the establishment of national sanatoriums on some insurance basis, such as is being done with success in Germany, combined with compulsory notification—not isolation—of tuberculous cases We can only arrive at this by gradually educating public opinion to such a pitch that the legislature will be compelled to move in the matter, and it is for you, and such as you, to do all that lies in your power in your practice hereafter to carry conviction on this question to the minds of everyone with whom you may come into contact.

REMARKS ON THE LIFE-HISTORY OF FILARIA BANCROFTI AND FILARIA IMMITIS

By LOUIS W SAMBON, M D NAPLES.

UNDER the title, "Sul Ciclo Evolutivo della Filaria Bancrofti (Cobbold) e della Filaria Immitis (Leidy)"[1] ("Remarks on the Life-cycle of Filaria Bancrofti, Cobbold, and Filaria Immitis, Leidy"), Dr Giovanni Noè describes more fully certain researches on the life history of filaria immitis which he had already published together with Professor Grassi in the *Rendiconti della R. Accademia dei Lincei* on August 25th, 1900

---

[11] Edinburgh Medical Journal 1901

[12] Brit Med Jour 1901 vol ii p 1

[1] Ricerche fatte nel Laboratorio di Anatomia normale della R Università di Roma ed in altri Laboratori Biologici, vol viii fascicoli 3 e 4

The mention of filaria Bancrofti in the title of Dr Noè's paper is not on account of any new observations made by Professor Grassi or Dr Noè on the development of this important parasite of man as one would naturally imagine but, apparently, only to enhance the value of the paper. In fact, Dr Noè introduces his work with the following preface: 'The subject I have been studying under Professor Grassi's guidance, is certainly one of the most important problems that medical science has ever submitted to the investigations *of zoology because the presence of blood filariæ in the body* of man gives rise to fearful and incurable diseases against which all attempts at an efficient prophylaxis have hitherto been vain, for the mode of entrance of these nematodes into the human body was unknown. The Italian discovery now at last enables us to place the prophylaxis of filariasis on a solid base, indicating the mechanical prevention of mosquito bites, suggested by malaria prophylaxis, as the best means of protecting man from this terrible scourge of tropical countries.'

Dr Noè's assertion that the mosquito propagation of filariasis has been discovered by Professor Grassi and himself or is an 'Italian discovery" as he puts it is, to say the least surprising and Professor Grassi should be the very last man to claim on the analogy of filaria immitis, the merit of having established a scientific basis for the prophylaxis of filaria Bancrofti seeing that he denied to Major R. Ross similar claims for the establishment of the scientific prophylaxis of malaria on the contention that Ross had only definitely proved the mosquito propagation of Hæmamœba relicta, a parasite of birds.

In a short historical sketch of the progress of investigations on the life-history of filaria Bancrofti, Dr Noè mentions how Dr P Manson discovered in 1877 that certain mosquitoes acted as intermediary hosts to filaria Bancrofti, and he rightly ascribes Dr Manson's hypothesis with regard to the conveyance of the metamorphosed larvæ to man to the erroneous notions entertained at that time by zoologists on the life-habits of mosquitoes. He also reports T L Bancroft's suggestion made in 1889 as to the possible propagation of filariasis either by the ingestion of infected mosquitoes or through the instrumentality of their puncture. He takes opportunity to ascribe again incorrectly, to Professor Grassi the discovery of the mosquito propagation of the malarial parasites of man and states that the researches of Major R. Ross on the transmission of hæmamœba relicta did not preclude the propagation of the parasites by means of air and water. Then he refers to a visit which Dr Manson and I paid to Professor Grassi in 1900 but the purport of that visit is misrepresented both in Dr Noè's paper and in the previous publication by Professor Grassi and Dr Noè.

Firstly Dr Manson went to Rome to investigate on the possibility of carrying out a double experiment on the etiology and prophylaxis of malaria in the Roman Campagna and, in fact, the experiment was successfully carried out by myself and Dr G C Low on the following epidemic season. Secondly Professor Grassi did not discover in Dr Manson's specimens a filaria at its maximum stage of development within the head section of a mosquito and did not formulate thereat the hypothesis of the possible transmission of filariæ by means of mosquito-bites for the simple reason that Dr Manson purposely brought his specimens from London to show Professor Grassi and others that filaria Bancrofti, after having reached a certain stage of development migrated from the thoracic muscles of its intermediary host most probably to reach the mouth parts of the insect and to be inoculated to the human definitive host during puncture as is the case with the malaria parasites. The same specimens had been shown previously to the Fellows of the Royal Society in London to Professor Blanchard in Paris and to Professor Celli, Professor Marchiafava, Professor Dionisi, Professor Bignami, Professor Bastianelli Dr Plehn, and Dr G S. Brock in Rome. Dr Noè states that Professor Grassi lecturing in the following March on comparative anatomy in the University of Rome, mentioned the possibility of the transmission of certain filariæ by means of the bite of infected mosquitoes but I fail to see the bearing of this remark on the claims of priority advanced by Professor Grassi and Dr Noè. Soon after Major Ross's discovery of the mode of transmission of the hæmamœbidæ everyone at all conversant with the study of filariasis at once grasped the possible analogy. If mere statements of opinion were of any scientific value I might well claim priority because in an article on Ticks and Tick Fever published the *Journal of Tropical Medicine* in April 1900 I stat quite positively that filaria Bancrofti was inoculated to m by infected mosquitoes. That statement was the expressi of a firm conviction based chiefly on Dr Manson's observ tions and on the analogy of the malaria hæmocytozoa, but was premature and therefore regrettable.

During the visit aforementioned, Professor Grassi stat that he had found a filaria, so far undetermined within t *Malpighian tubes of anopheles maculipennis* and of cour he agreed with Dr Manson on the possible transmission those nematodes by means of the bite of their intermedia hosts. Next a letter from Dr Manson to Professor Gras announcing the finding of filaria Bancrofti between t labium and the mandibles in sections of artificially infect mosquitoes is dismissed with the most uncalled for rema that Dr Manson, the foremost authority on filariæ h probably mistaken other nematodes for filariæ. Howev says Dr Noè even allowing the correctness of Dr Manso observations, they do not prove the direct inoculation filariæ from mosquito to man because the mosquitoes mig deposit the filaria larvæ in the water while resting on surface to drink or lay their eggs." Lastly Dr N discusses Dr Low's paper on the result of sections ma for Dr Manson of artificially infected mosquitoes receiv from Bancroft and he accuses Dr Low of having erroneous supposed the labium *to be closed at its base* while is really a continuation of the lacunoma. From an examin tion of the drawings illustrating Dr Low's paper Dr N maintains that the filariæ described by Dr Low as free w still inclosed within the labium and he adds The filari have no perforating organ and are therefore unable to pier the tough chitinous case of the labium. He furth attempts to prove that both Dr Manson and Dr Low we very uncertain about the mosquito inoculation of filar Bancrofti because Dr Low entitled his paper Probab Mode of Infection," and because Dr Manson, in an artic published in the *British Medical Journal* on Sept. 1st 190 says 'The subject of filariasis is by no means worked out and remarks that the filariæ may leave their insect host b some other channel than the proboscis."

Having thus settled to his own satisfaction that nothi was proved as to the transmission of filariæ from inte mediary to definitive host *previously* to his own research and to those of Professor Grassi Dr Noè passes to consid the history of filaria immitis. He mentions that Calandrucci in 1892, discovered certain filariæ in the stomach of mosquito and supposed them to be the larvæ of filari immitis because, having examined the domestic anima kept in the house where the infected mosquito was capture Calandruccio found a dog the blood of which was swarmin with embryos of filaria immitis but Dr Noè considers Cala druccio's discovery as null because Calandruccio was unab at the time to make any further investigation on the subje and because he did not identify the mosquito which he ha dissected.

In the following chapter we are told how Professor Gras discovered that anopheles maculipennis is the usual inte mediary host of filaria immitis in Italy. Of cour this discovery was neither prompted by Calandruccio *observation nor suggested* by Dr Manson's work on th life-history of filaria Bancrofti, but was the outcome philosophical reasoning. Professor Grassi while studying th mosquito-cycle of the hæmamœbidæ, discovered the larv of a nematode in anopheles maculipennis. Some time pre viously Professor Grassi had discovered that the distributio of filaria immitis *in dogs coincided* with the *distribution o* malaria. Later he discovered that the distribution of ano pheles maculipennis coincided exactly with that of malaria therefore he concluded that the larval nematode found i anopheles maculipennis must be the early form of filari immitis.

Everybody knows now *full* well that the *distribution* o anopheles maculipennis does not coincide with that o malaria. There are many places even in Italy withou malaria where anopheles maculipennis abounds and ther are vast malarial regions where anopheles maculipennis i unknown. The same may be said of the distributiona coincidence of filaria immitis and malaria. Moreover anopheles maculipennis is not the only mosquito capable of fostering the larval stage of filaria immitis. Dr Noè himself found that in the neighbourhood of Rome anopheles pseudopictus, anopheles bifurcatus and anopheles super pictus are just as easily infected and he found several gnat of the genus Culex (culex penicillaris, culex malariæ) equally susceptible. However, whether guided by Calandruccio's indefinite observation or by erroneous conceptions of the distribution of anopheles maculipennis, of filaria immitis, and of malaria, it is a fact that Professor Grassi and Dr Noè have experimentally proved that anopheles maculipennis can foster the larval stage of filaria immitis

Now, let us examine the experiments made by Dr Noè to prove the inoculation theory of filaria immitis To obtain infected mosquitoes Dr Noè began by collecting at random female anopheles in any malarious locality, later he captured his specimens in the houses of Porto di Fiumicino (a small hamlet at the mouth of the Tiber) where, out of 10 dogs, six harboured embryos of filaria immitis. Of the anopheles thus collected at Porto less than 5 per cent were infected and only about 2 per cent. had fully metamorphosed filariæ. Finding this proportion totally inadequate, Dr Noè inclosed two filariated dogs in an ordinary reed hut and liberated in the same large quantities of anopheles gathered in various places Thus he was able to raise the proportion of infected mosquitoes to about 30 per cent The mosquitoes that had imbibed blood from the filariated dogs were afterwards kept in special boxes and fed on the juices of various fruit till ready for use The dogs experimented upon were, so far as could be ascertained from examinations of the blood, free from filarial infection

On July 19th, 1900, having obtained mosquitoes with filariæ in the labium, Dr Noè dissected two such insects in normal salt solution and placed the liberated filariæ at the bottom of an incision made in the skin of a dog over a year old in the blood of which filaria embryos had not been found. Sixteen days after the inoculation, the dog was killed, but after a whole day of the most minute researches by Professor Grassi, Dr Noè, and two other gentlemen, only a small portion of the anterior extremity of an adult nematode was found in the subcutaneous tissue near the genitals This fragment (three millimetres long) was, however, labeled "filaria immitis" on account of the existence of six papillæ round its mouth and was considered to have been derived from one of the parasites experimentally introduced. On July 20th, a second experiment was made in the same way by stuffing filariæ in a skin wound, but it proved negative.

In consequence of the finding in his first experiment Dr Noè considered the inoculation theory "sufficiently demonstrated." However, he endeavoured to obtain the inoculation of the parasites in the presumed normal way by means of the bite of infected mosquitoes and thus more befitting experiments followed in which dogs, to all appearances healthy, were inclosed at night with mosquitoes, a small proportion of which possibly harboured filariæ ready to be transmitted. The dogs were muzzled so that they should not swallow the mosquitoes and possibly become infected in this way At the same time three other dogs were fed on large numbers of mosquitoes gathered in various places or purposely fed on filariated dogs in the laboratory Moreover, a dog and a puppy were kept for one month at Porto together with the filariated dogs of the locality and in places swarming with mosquitoes Neither the dogs fed on mosquitoes nor those kept at Porto showed any signs of infection at the necropsy

The negative result in the dogs kept at Porto Dr Noè explains by supposing that the dogs did harbour filariæ, but that they were killed too soon and that the worms escaped research on account of their diminutive size. The negative result of the feeding experiments, on the other hand, is triumphantly brought forward as "absolutely proving that infection cannot take place through ingestion as suggested by Manson" Why the explanation given in the case of the dogs kept at Porto should not be equally applied in the case of dogs fed on mosquitoes is not quite clear One of the three dogs subjected to the feeding experiment was killed after eight months but the other two were killed after one month and two months respectively And here I must say that Dr Noè in stating that Dr Manson suggested the ingestion theory is incorrect, because it was Dr Manson who suggested the inoculation theory and it was through him that the first and most suggestive evidence was produced. But Dr Manson has worked at filariæ for more than 20 years and he has acquired that true scientific spirit of caution which seems to be wanting in Dr Noè We shall see further how Dr Manson's reservations are fully justified by the observations of Dr Noè himself

The following are the experiments reported by Dr Noè in which mosquitoes (anopheles maculipennis) supposed to contain fully metamorphosed filariæ were made to bite dogs apparently immune from filarial infection 1. A bitch bitten on July 19th by two anopheles was killed in August, the result was negative 2. A dog bitten on July 26th and several times after that date by many anopheles, it was killed in October, the result being negative 3. A dog bitten on August 9th by eight anopheles was killed in October, the result was negative 4 A dog was bitten on August 23rd and 24th by anopheles gathered at Porto On Dec 5th some few embryonic nematodes were found in its blood and Dr Noè, mistaking them for the embryos of filaria immitis, supposed them to have been derived from the inoculated filaria and published the experiment as successful [*] Early in February, 1901, this dog was killed, but notwithstanding the most careful researches during four whole days no adult filariæ were found, and Dr Noè was obliged to suppose that the embryos found in the peripheral circulation of this dog must have been those of some other nematode, possibly those of filaria recondita, a parasite the location of which has, so far, escaped investigation 5 A dog, two years old, was bitten on August 23rd and 24th, 1900, by anopheles infected on a filariated dog in the laboratory Early in the following February embryos similar to those of the previous dog were found in its blood This dog was killed on April 12th. After a very careful search one immature female filaria immitis was found in the subcutaneous connective tissue. It measured six centimetres, contained no embryos, and to all appearances had not been fertilised This filaria had evidently nothing to do with the embryos in the blood. Besides, the latter were much smaller than the embryos of filaria immitis, they showed peculiar spring like movements, and were provided with an erectile spine at the anterior extremity 6 A small bitch was bitten several times between Oct. 15th and 20th, 1900, by anopheles captured at Porto It was killed on April 14th, 1901, although no filaria embryos had ever been found in its blood Nine adult filariæ were found, eight in the connective tissue and one in the pericardium All were sexually mature. The females had been fertilised and they contained numerous embryos but they had not yet commenced parturition. The longest males measured five centimetres and the longest females 11 centimetres 7 A dog, bitten in August, 1900, by anopheles collected at random in various localities, was killed on Sept. 3rd, 1901. A female filaria immitis was found in the subcutaneous connective tissue, but the worm had not been fertilised and no embryos of any kind had ever been found in the blood of the host.

Of these seven experiments Nos 1, 2, 3, and 4 were negative, but Nos 5, 6, and 7 were considered to be positive, because one or more filariæ were found at the necropsy On account of the last three experiments Dr Noè concludes "It is fully demonstrated that the filariæ enter their definite host by means of the bite of mosquitoes" The negative experiments he explains by supposing that the experiment-mosquitoes were probably not infected or that the inoculated filariæ were not detected at the necropsy of the dogs on account of their diminutive size, the hosts having been killed too soon

The crudeness of the above mentioned experiments might be somewhat explained if the experiments had been instituted by Dr Noè alone, who was at the time only a student, but we are told that they were carried out in Professor Grassi's laboratory and under his tuition, and, indeed, they were first published in the name of both The methods of the attempts to procure infected mosquitoes and the extraordinary carelessness shown in the choice of suitable dogs, are most surprising, especially in a man who was supposed to have gained some appropriate experience during the researches he made while studying the mosquito propagation of the malaria parasites The mosquitoes for the experiments should have been reared and infected in the laboratory and the dogs should have been puppies born after the end of the last season of infection (October) and carefully guarded from every possible source of infection till the time of experiment Instead of which we find Dr Noè experimenting with non-infected mosquitoes and with dogs, two and more years old, already harbouring various species of filariæ.

Of the two experiments in which filariæ were inserted into skin wounds one is reported as successful and the other as negative In the experiment considered to have been successful only a small fragment of a nematode was found. We are told that it proved sufficient for the identification of the parasite, but I doubt this very much and my doubt is not a retort to the insinuation made by Dr Noè that perhaps the nematodes described by Dr Manson were not filariæ, but is very justly based on Dr Noè's most awkward mistakes. In fact Dr Noè owns himself that he mistook the embryos of some other nematodes for those of *filaria immitis which he, a zoologist, had been studying for* nearly two years, but another very bad mistake is found at page 325 where, after stating that filaria immitis at its maximum stage of development within its intermediary host measures about 900μ, he adds that once he found one that had attained the enormous length of two centimetres. Dr Noè found this filaria amongst the thoracic muscles of an anopheles and explains its gigantic proportions by its unusual location which must have caused a long permanency in the body of the mosquito. While in the Roman Campagna Dr Low and I found similar filariæ in the thoracic muscles of anopheles maculipennis, but time and circumstances prevented us from determining the definitive host of these nematodes. However the greater dimensions of those parasites and the different location for their development suggest at once a specific distinction.

---

[*] Rendiconti dell Accademia dei Lincei vol ix 2 sem, serie 5 fasc 12.

Even allowing that the identification of the tiny bit of worm was possible and absolutely correct, it is not by any means proved that it was derived from one of the artificially introduced filariæ. It was ascertained that the dog at the time of the experiment had no filaria embryos in its blood but it was not proved that it did not already harbour young filariæ in its tissues.

In experiment No 6 of the series, in which anopheles *supposed* to be infected were made to bite dogs *supposed* to be non infected nine sexually mature filariæ were found six months after the date of *supposed* infection. In experiment No 5 a filaria only half grown was found at the post mortem examination eight months after the date of experimental inoculation and in experiment No. 7 a filaria still immature was found 13 months after experimental inoculation. Supposing for one moment that the immature filaria found in experiment No 7 had really been derived from one of the larvæ inoculated 13 months previously it would be difficult to understand how in experiment No 6 the filariæ could *have reached full maturity in less than six months*

From what I have said it is clear that no account can be taken of Dr Noè's experiments but Dr Noè mentions an observation of a different kind by which he says he obtained quite unexpectedly a most definite proof as to the direct inoculation of filaria by means of the bite of mosquitoes. On July 25th he gathered a large batch of anopheles. On August 5th he examined a number of these mosquitoes and ascertained that some of them were filariated. On the 10th he examined the remaining mosquitoes but did not find a single filaria in any of them. Supposing that the mosquitoes might have lost their filariæ while feeding on fruit he looked for the nematodes in the fruit pulp on which the mosquitoes had fed but was unable to find any On the 23rd, having found filariæ in the labium of certain mosquitoes out of a large quantity which had been fed on the 10th and 11th of that month on a filariated dog he closeted some of these mosquitoes all night with a healthy dog (experiment 4 or 5) On the next morning *these* anopheles were heavily gorged with blood. On dissection he did not find a single filaria in any of them, but he says that he found in their Malpighian tubes lesions undoubtedly significative of filarial infection. He at once examined the remaining mosquitoes and found that five out of 11 contained filariæ in their labia and showed in their Malpighian tubes changes similar to those of the gnats previously examined. Thereupon Dr Noè concluded that the anopheles which had bitten the dog must have emptied out their parasites during puncture and that the remaining anopheles of the previous batch which on August 10th had no filariæ while others of the same batch five days earlier had been found infected must have emptied their larvæ in the fruit pulp and that the liberated filariæ must have escaped detection on account of their very minute size.

This observation is, like the others, most unsatisfactory We know that only a certain proportion of the mosquitoes employed were infected it is quite possible therefore that those dissected after biting the dog or feeding on fruit were the non infected ones Admitting that those in which Dr Noè say he found lesion of the Malpighian tubes were really infected it is in no way proved that the filariæ were liberated during puncture and not evacuated with the fæces. Dr Noè was unable to demonstrate the presence of filariæ in the fruit pulp and his experiments upon dogs, as we have already seen are totally untrustworthy Against Dr Noè's surmise as to the liberation of filariæ in fruit during puncture stand the observations of T L. Bancroft and Dr Low which prove the contrary Besides Dr Noè himself in another part of his paper says that to obtain the liberation of the filariæ *the labium must bend and rupture* In the case of fruit, when the insect can absorb the juices at the surface without thrusting the stylets to any depth, and therefore without bending sufficiently the labium, the liberation of the parasites does not take place Then again, how is it that all the mosquitoes examined had emptied all their filariæ simultaneously while Dr Noè states that the parasitic larvæ do not reach maturity all simultaneously but successively and that, therefore, this migration to the mouth parts of the host takes place by 'successive stages.

In fact, he says I have frequently observed that after an emission of parasites the Malpighian tubes still contain a certain number of filariæ ready to leave in a short lapse of time their larval seat. It is obvious therefore, that the labium becomes again gradually invaded by and stuffed with, filariæ and that thus a second emission may take place on a subsequent puncture. Thus the mosquitoes when abundantly infected may have the power of inoculating the parasites two and perhaps even more times."

Now leaving aside Dr Noè's contradictions and admitting for a moment that as he believes, the filariæ might escape from their intermediary hosts while the latter imbibe the juices of fruit we obtain a strong proof of the judiciousness of Dr Manson's caution in writing that the fact of the presence of the filaria in the proboscis of the mosquito suggests without actually proving that the parasite is directly inoculated into man by mosquito-bite At the same time we must remember that the fully metamorphosed filaria is sometimes found around the stomach about the viscera, and elsewhere than in the head of the mosquito. It is quite possible, therefore, that it may leave the insect by some other channel than the proboscis and it may be passed into water with the fæces, the eggs or even by the proboscis Finally Professor Grassi and Dr Noè claim to themselves the discovery of the inoculation theory of filariasis because, they say Dr Low was not able to prove how the filariæ escaped from the labium. They suggest that the filariated labium tears towards the middle of its dorsal aspect while bending during puncture But this is nothing more than a hypothesis and Dr Noè himself says I think that an absolute certainty is difficult to obtain on this point because, as everyone understands one would have to surprise the filariæ in the act of escaping during the opera*tion of the puncture, and this is far from easy* " T Everett Dutton has suggested a far more rational point of escape at the tip of the labium, between the labellæ. This area is covered by a very delicate membrane which tears very easily and is practically over the point of puncture when the mosquito draws blood—a very important condition to insure the inoculation of the liberated filariæ. Personally I believe that the filariæ pass into the wound along the dorsal groove of the hypopharynx having reached the mouth cavity by *piercing the delicate membrane which connects the chitinous* pharynx to the base of the hypopharynx, and I believe that their presence within the labium has no other significancy than that of their presence within the palpi which is just as frequently observed. However this may be, the hypothesis advanced by Professor Grassi and Dr Noè is certainly the least probable.

I think that it is to be very much regretted that Dr Noè did not limit his paper to the researches which he *made on* the development of filaria immitis in anopheles maculipenni His observations on the structure of this parasite during its larval development are certainly accurate I do not agree with any of his interpretations but that is perhaps a matter of opinion. For instance Dr Noè thinks that the jutting posterior intestine of the filaria in its early stages becomes an organ of adhesion and fixes the parasite to the cells of the Malpighian tubes. I think instead that it subserves the function of nutrition If we examine the filaria larva between the sixth and ninth day of its development within the Malpighian tubes of a mosquito we find that its posterior intestine does not communicate with the rest of the alimentary apparatus but forms a completely closed bladder like body part of which projects outside the body of the worm into the cytoplasm of the host to absorb nutriment and, indeed, the vesicle gradually fills with a clear, transparent fluid Besides, on the ninth day or thereabouts the chyliferous intestine becomes connected with the posterior intestine and the protruding part of the latter opens to form the anus Thenceforth the filaria feeds by the mouth

Dr Noè has observed that the filariæ undergo at times a brown degeneration within the Malpighian tubes of their host and, true to the traditions of the Roman school, he believes this degeneration to be a retrogressive process of the parasite. This so-called brown degeneration begins by scattered brown spots which under a strong magnifying power have a lenticular shape. The spots gradually increase in number and coalesce into large dark brown patches These brown bodies may appear on a few or on all the filariæ contained in one or in all of the Malpighian tubes of a mosquito They are no other than the "black spores" described first by Major Ross in connexion with the hæmamœbidæ I believe that they represent a parasitic infection comparable to the pebrine disease of silk worms

Dr Noè closes his paper with a most extraordinary remark. He recognises that the prodigious fertility of filaria immitis is an admirable adaptation for the perpetuation of the species, but he explains its operation in a way which seems to me to be far more original than reasonable. He says that the mosquitoes become so easily infected that if numbers of them did not die the canine species would soon become totally extinct and with the disappearance of dogs the filariæ would necessarily also disappear, therefore, to avoid such a disaster the filariæ have excogitated the admirable means of killing off their necessary intermediary hosts by a prodigious fertility and consequent heavy infection. Dr Noè explains the passage of the filaria from definitive to intermediary and from intermediary to definitive hosts in a totally passive way and I will not ask him why other filariæ develop in other parts of the mosquito instead of gravitating, like *his* filaria immitis, first into the Malpighian tubes when the mosquito sits up after its meal, and then into the labium when the latter comes down again head foremost to draw blood, but I feel that I must protest against the stigma of suicidal mania which he casts on the worm, forgetting the universal significancy of an enormous fertility which is common to numberless species, and forgetting that the domestic dog may possibly not be the only definitive host of filaria immitis and that filaria immitis, although widely distributed, is strictly limited to certain swampy stations

SOME FURTHER STATISTICS REGARDING THE EFFECT OF INOCULATION AGAINST TYPHOID FEVER IN SOUTH AFRICA,

WITH SPECIAL REGARD TO THE QUESTION OF AGE.

BY ALEXANDER CROMBIE, M D EDIN,
LIEUTENANT-COLONEL, I.M.S (RETIRED)

IN THE LANCET of May 3rd, 1902, at p 1241, will be found the statistics of 250 officers invalided from South Africa for various causes. These figures showed a higher percentage incidence of typhoid fever among the inoculated (28 5) than among the non inoculated (22 0), and it was pointed out that this might be due to a higher rate of recoveries among the inoculated I do not propose to discuss the figures which might be adduced in support or otherwise of this opinion My figures also showed that the average date of attack after disembarkation in South Africa was shorter among the inoculated (9 4 months) than among the non inoculated (10 3 months), but that the non inoculated were more susceptible during the first five months after disembarkation than the inoculated. The inference to be drawn from these figures was that inoculation conferred a certain measure of protection for a period of about six months After that period the inoculated appeared to suffer more than the non inoculated I hinted that these differences indicated the operation of some law affecting the figures

The publication of these statistics led to a correspondence with Professor Wright of Netley who suggested that the law referred to was probably that of age and susceptibility He thought it probable that the inoculated would be found to be younger men than the non inoculated and that the higher incidence among the former after the six months of protection afforded by inoculation had passed was in all likelihood due to the re assertion of their greater susceptibility on account of their comparative youth I had not recorded the ages of the 250 officers who furnished the statistics and I accordingly commenced a new series of observations with a view to ascertain what truth there was in Professor Wright's suggestion. The following figures are the result of this inquiry Table I shows that the average age of the inoculated was 25 4 years and that of the non inoculated was 30 6 years, a difference of five years The incidence of typhoid fever among the former was 33 3 per cent. and among the latter 32 9 per cent

TABLE I.—*Showing the Average Age of the Inoculated and Non inoculated*

—	Number	Average age (years)	Cases	Per cent
Inoculated once	89	25 4	24	26·9
" twice	13	25 5	10	76 9
Total inoculated	102	25·4	34	33 3
Previous attacks	19	32 1	3	15 8
Not inoculated	85	30·6	28	32·9
Totals	206	28·2	65	31 5

The figures in Table I show a distinct advantage in favour of a single inoculation, but they indicate a strong susceptibility to enteric fever among those who were inoculated twice. In this series 10 out of 13 officers who were inoculated twice on the outward passage contracted typhoid fever after disembarkation in South Africa. In my first series the proportion attacked was smaller, two in 10 Taking the two series together it will be found that of 23 double inoculations 12 were infected, or over 50 per cent., as against 33 per cent among the non inoculated I do not think that a difference of age amounting to five years would account for this greater incidence, and it is possible that the double inoculation is excessive and diminishes the resisting power of the blood to infection. The incidence among those twice inoculated is just double that among the once inoculated, and such a result would not be in discord with some of Professor Wright's more recent experimental work

In the following tables (Tables II, III, IV, and V) the incidence in relation to age is shown in detail They show that 60 per cent of the inoculated were under 26 years of age, against 22 per cent among the non inoculated The incidence at this age among the non inoculated was 63 4 per cent, among those inoculated once 27 8 per cent., and among those inoculated twice 71·4 per cent. This gives a *difference of 35 per cent. in favour of a single inoculation* at this age, which must be regarded as a very substantial gain. Between the ages of 26 and 35 years the number of inoculated constituted 31 per cent. of the total inoculated, against 50 per cent among the non inoculated At these ages the incidence among 42 non inoculated was 31 per cent., among 27 inoculated once 22 per cent., and among five inoculated twice 80 per cent. Here there was a gain of 9 per cent. among those inoculated once

TABLE II —*Inoculated Once*

Age in years	Number	Cases	Per cent.
17–20	28	5	17·8
21–25	26	10	38 4
26–30	16	4	25·0
31–35	11	2	18 2
36–40	5	1	20·0
41–45	3	2	66 7
Average age 25 4	89	24	26 9

TABLE III —*Inoculated Twice*

Age in years.	Number	Cases.	Per cent.
17-20 ..	5	4	80·0
21-25	2	1	50·0
26-30	3	2	66 7
31-35 ..	2	2	100·0
36-40	1	1	100·0
Average age 25·9	13	10	70·9

TABLE IV —*Total Inoculated*

Age in years	Number	Cases.	Per cent
17-20 ..	33	9	27·7
21 25 ..	28	11	39·3
26-30	19	6	31·6
31-35	13	4	30·7
36-40	6	2	33 3
41-45	3	2	66·6
Average age, 25·6	102	34	33 3

TABLE V —*Non inoculated*

Age in years	Number	Cases.	Per cent.
17-20	10	5	50·0
21-25	9	7	77·7
26-30	24	10	41 7
31-35	18	3	16·6
36-40	15	1	6 6
41-45	9	2	22·2
Average age 30·9	85	28	33 1

Above the age of 35 years the advantage was in favour of those not inoculated, of whom 28 per cent. were included in this section against 9 per cent. of the inoculated The incidence of enteric fever at this period of life was 12 5 per cent. for the 24 non inoculated 37 5 per cent. for the eight inoculated once, and 100 per cent. for the one individual inoculated twice—an advantage of 25 per cent. in favour of non inoculation over one inoculation. I am not in a position to offer any explanation of this remarkable outcome of my statistics.

For the more ready perception of the effect of inoculation at different ages I append in Table VI the differences observed in the incidence of the disease in the different classes taking that among the non inoculated as a standard at each quinquennial period

TABLE VI.

Age in years.	Incidence per cent.		
	Non inoculated	Inoculated once.	Inoculated twice
17 20	50·0	−32·2	+30·0
21-25	77 7	−39·3	−22·7
26-30	41 7	−16·6	+50·0
31-35	16·6	+ 1·6	+83·0
36-40	6·6	+13 4	+93·0
41-45	22·2	+44·5	
Average ...	33 1	− 6·2	+43·8

These tables show that the period of greatest susceptibility to enteric fever is from 20 to 25 years of age. This was true for the inoculated as well as the non inoculated but it was precisely at this period that the evidence of the protective effect of inoculation was most marked. Up to the age of 30 years the advantage of a single inoculation is distinct, the incidence in this class being 27 per cent. against 51 per cent among those not inoculated Beyond the age of 30 years the position is reversed and the advantage is with the non inoculated, the incidence among them being then only 14 3 per cent against 27·4 per cent. among those inoculated once These figures would seem to suggest that as the period of natural susceptibility to the disease is passing away inoculation is to be avoided as likely to increase the liability to infection. The whole question of immunity and the effect of inoculation on immunity is evidently and admittedly a most difficult and complicated one I am glad, however to be able to point out by these statistics the unmistakeable evidence which they afford of the clear and substantial advantage a single inoculation gives to the young soldier under the age of 30 years and especially at the age when his susceptibility to the infection is greatest.

With regard to the period which elapsed between disembarkation in South Africa and the attack the average for those not inoculated was 14 4 months for those inoculated once it was 11 8 months for those inoculated twice it was 7 7 months and for those who had had a previous attack of enteric fever 11 months These periods bear the same relation to each other as in my previous series of cases. The advantage of the non-inoculated in this respect is doubtless to be accounted for by their greater average age and consequent lower susceptibility The early attack of those inoculated twice is corroborative of the opinion expressed above that a double inoculation increases the susceptibility to infection

Bickenhall mansions W

THE TREATMENT OF APPENDICITIS

BY JOHN O CONOR, M.A. M D DUB.,
SENIOR MEDICAL OFFICER, BRITISH HOSPITAL, BUENOS AYRES.

IT may be of some interest if I endeavour to report the practical conclusions derived from 140 operations for appendicitis. In order that no misunderstanding may arise I will commence by quoting an extract from Sir Frederick Treves s excellent work on Surgical Applied Anatomy " which I consider fully illustrates the complex anatomical nature of the infection and the difficulties which must necessarily attend clinical diagnosis. *The mesentery of the appendix* which contains an artery derived from the ileo-colic, may be so short as to produce obstructive kinks in the appendix. The mucous lining is so crowded with solitary lymphoid follicles as almost to occlude its lumen. In some forms of appendicitis these follicles are involved. They are surrounded by lymph spaces from which vessels pass to the lymph glands in the mesentery and others pass upwards behind the ascending colon (Lockwood). It is probably through these latter vessels that infection passes from the appendix and gives rise to abscesses in the subdiaphragmatic region The muscular coat of the appendix is scanty and through breaks in it the submucous tissue communicates with the subserous Inflammation of the mucous membrane may therefore, spread without hindrance to the peritoneum. At present there are three operative procedures in vogue for purulent appendicitis—cœliotomy and drainage without subsequent removal of the appendix cœliotomy with drainage and secondary appendicectomy, and cœliotomy removal of pus separation of adhesions and appendicectomy at the same time. The advocates of the first method have not as yet got rid of the erroneous idea that in the wreck of matter attending abscess formation destruction of the appendix not infrequently occurs. Personally I never believed in such a doctrine and I have had ample practical proof that the appendix never completely disappears without the help of a surgical instrument, but I have frequently operated on cases in which the organ appeared to be transformed into a kind of fibrous cord which by the way was invariably adherent to something and caused the patients continual indigestive worry which can be explained by its tent-rope action on a distensile and sluggish cæcum

On three occasions I have had to remove the appendix during a recurrent purulent attack in patients who had incision and drainage performed by other surgeons years before and in each instance I found the appendix entire. In four of my early cases, from want of experience, I abandoned the appendix. The first patient discharged pus for 18 months, at the end of which he not unnaturally sought other advice and I have not heard of him since (The other day I saw Mr Lockwood operate on a case which had discharged for 12 months after incision and drainage) The second patient had a very large incision made as there was a huge iliac abscess, the wound took 10 weeks to heal About a year afterwards a hospital surgeon in Scotland wrote to me inquiring what was the meaning of such a large cut and what was my diagnosis as the patient had entered under his care with what appeared to be an attack of purulent appendicitis The third patient returned within three months, very much disgusted, with a recurrent attack. On separating some dense posterior cæcal adhesions I found a decomposing prawn like appendix tucked up behind the cæcum I have little doubt that in this case a smouldering fire continued since the primary attack. (I recently saw Mr Burghard operate on a case during what the absence of any symptoms declared to be in the "quiescent' stage, he found the appendix deeply adherent and its distal half was literally converted into a bag of pus.)

The fourth case was very interesting in that the site of the abscess differed on each occasion At the first operation a large fœtid abscess was found external to the cæcum and colon, three and a half years later the patient returned to hospital complaining of intense pain and tenderness in the right lower abdomen On palpation a large tumefaction was readily detected On opening the parietal peritoneum I was surprised not to meet with any pus, instead, a mass of thickened inflamed adherent omentum presented On separating this from underlying intestines I discovered a large intra intestinal tumour completely covered over by coils of bowel Having packed all round I separated the adhesions between the cæcum and the ileum and evacuated about a quart of foul green pus, and at the bottom of the abscess cavity I found a gangrenous perforated appendix, about five inches of an adjacent coil of ileum was gangrenous on its under surface and tore right across on separating the appendix from it. As the patient showed signs of collapse at this stage of the procedure two 10 minim injections of liquor strychnine were administered as well as a warm enema. I rapidly removed the appendix and then excised some six inches of gangrenous gut, including my tear, a Murphy button was inserted As there was intense shock, 10 minim injections of strychnine were given every half hour for the succeeding three hours, reaction took place and an uneventful recovery ensued The button was passed on the nineteenth day and when the nurse exultingly showed it to him he replied "It was right enough where it was" I believe that the strychnine saved his life, and since I first read of the treatment in Baldy's "Gynecology" I have used it constantly in cases of shock with the best results I like to see a little muscular twitching as it indicates that a sufficient dose has been administered.

The following case occurred in the practice of a colleague A middle-aged man suffered from a primary attack of purulent appendicitis Owing to the dread of operation hot poultices were applied for some six weeks As nothing had burst by this juncture his medical attendants persuaded him to allow them to make "a little cut just big enough to let out the matter," which they said was devoid of risk This was done and the toxic symptoms rapidly disappeared. The purulent discharge had almost ceased 10 days later and one day as the surgeon was leaving the room after changing the dressing the patient said that he ' felt wet." On removing the bedclothes the dressings were found to be saturated with blood and he rapidly succumbed, pressure and plugging proving futile As no post-mortem examination took place the cause of the catastrophe remains uncertain, but one cannot help thinking that if a complete operation had been performed the infection would not have travelled into and ruptured presumably, the iliac vein.

The following is an interesting example of the inefficacy of suppuration as a cure for appendicitis A young woman suffered from purulent appendicitis in 1895, poultices were applied for two months when a large discharge of pus took place by the rectum After this she continued to have recurrent attacks of pain occasionally accompanied with fever and rostration and suffered very much at each menstrual period th severe pain in the right pelvis After five years of such try she resolved to have the matter settled "one way or r" and insisted on having a radical operation performed uld be difficult to describe the labyrinth of dense adhesions in which I found myself, omentum, bowels, fibrous cord like appendix, right tube and ovary, uterus, left appendage, and rectum forming a conglomerate of which I have never seen the like After a most trying ordeal and at the expense of much intestinal peritoneum I effected separation of the above structures, performed appendicectomy, right oöphorectomy, excision of a large mass of omentum, and concluded by fixing the uterus to the lower angle of the parietal wound, and by suturing over all the denuded surfaces of the bowel. A desperate peritonitic struggle followed on the fourth and fifth days which, luckily, was got over by purgation. A year later I had to remove some silkworm gut ligatures from a sinus which tracked down to the bottom of the pelvis She is now quite well

Particular attention must be devoted to the treatment of intra intestinal appendical abscesses If the whole mass cannot be delivered through the wound the field must be thoroughly exposed and isolated by gauze packing before adhesions are separated, and any laceration of intestinal serous membrane must be subsequently repaired by a few Lembert sutures Occasionally patients reproach one for the length of scar or for a subsequent ventral hernia. I can generally appease the cosmetic indignation of the fashionable lady by replying that both afford strong evidence that I saved her life

One has next to consider the expediency of the second method which is unquestionably a step in advance of the above-mentioned one in that the danger attending the derelict appendix is fully recognised, but it fails in the assumption that risk is removed by a subsequent appendicectomy in the "quiescent" period The reason usually assigned for this two stage procedure is that there is a great danger of setting up diffuse septic peritonitis by separating adhesions in the presence of pus I do not think such a fear is founded on fact, for I have at least on 100 occasions separated peritoneal adhesions after removing free pus and in no instance has such a complication supervened The supposed risk is a mere nightmare developed from a faulty appreciation of the function of an adhesion The formation of inflammatory adhesions is nature's method of staying the advance of infection and acts as a temporary barrier until one of three things occurs—the abscess empties itself somehow, the patient dies from sepsis, or the surgeon intervenes and relieves the adhesion of all further responsibility, and this is amply proved by the fact that peritoneal adhesions usually disappear after the exciting cause is removed. Under no condition excepting impending death on the table, or a most enfeebled constitution do I admit that a retreat before a friendly adhesion is justifiable without the removal of the cause of infection, and, furthermore, I consider that the greater the density of the adhesion the greater the necessity for pushing home the attack, for it may be taken as a general rule that the density of adhesions is in due ratio to the intensity of primary trouble. The following are excellent illustrations of the futility of attempting to treat a case of purulent appendicitis without separation of adhesions, as neither pus nor appendix can be dealt with without doing so

CASE 1—An American, aged 68 years, while crossing the Andes was seized with an acute attack of purulent appendicitis On opening the peritoneal cavity no parietal serous adhesion or pus was met with, but a moveable tumour surrounded by congested adherent intestines presented. Realising the probability of an intra-intestinal appendical abscess I delivered the whole mass through the parietal wound, and on separating adhering bowels an abscess containing some 12 ounces of offensive pus was evacuated and at the bottom of the cavity I found a suppurating appendix. Free drainage was provided and a rapid recovery ensued

Cases 2, 3, and 4 were identical in that, as no pus was found until a thickened adherent mass of omentum was separated from the cæcum and in each instance I found a partially gangrenous appendix lying in a circumscribed pool of fœtid pus, appendicectomy with drainage was performed All the patients recovered

CASE 5—A man occupying an important position in a company entered hospital for an operation for appendicitis The omentum was adherent to the parietal wall and to adjacent intestines When freed the cæcum was found to be glued to the ileum which when separated revealed a small intra intestinal abscess and a gangrenous perforated appendix with a gall stone (of about the size of a cherry stone) working its way out through the perforation

Appendicectomy with drainage was performed. Recovery ensued.

CASE 6.—A boy aged 13 years, was operated on for what I considered to be an attack of "simple" appendicitis. I had great difficulty in finding the appendix, which was adherent behind the cæcum, surrounded by a tablespoonful of pus. (On post-operative examination a small gall-stone was discovered near the distal extremity of the organ.) Recovery ensued.

I may here mention that these were the only foreign bodies I have met with in my series of cases.

CASE 7.—A sailor entered the hospital suffering from an obvious appendical abscess in the right iliac fossa. When the peritoneum was incised about one and a half pints of pus escaped. Having carefully dried the cavity I proceeded to search for the appendix and on liberating some omentum which was adherent to the cæcum and the pelvic brim a large pelvic abscess was found. Appendicectomy was performed and recovery ensued. In this instance the adherent omentum formed a partition between the two collections of pus.

CASE 8.—A patient was operated on for a large appendical abscess which filled up the right fossa. After evacuation of the same I found the cæcum densely adherent posteriorly and on freeing the adhesion opened into a small post cæcal abscess which contained a gangrenous appendix. Recovery ensued.

CASE 9.—A young woman, aged 21 years, was operated on for what I took to be "simple" appendicitis. On opening the abdomen I discovered nothing except a small intra-intestinal tumefaction of about the size of a plum. On separating the adherent coils a small fæcal abscess was found as well as a gangrenous perforated appendix and three infective concretions loose in the cavity. Appendicectomy was performed and recovery ensued.

These cases cannot be considered in any way exceptional for as Sir Frederick Treves states "the appendix, as a rule is seen to lie behind the end of the ileum and its mesentery and to point in the direction of the spleen; it frequently also lies behind the cæcum." From this it is obvious that any surgeon who counts on meeting the appendix externally to the cæcum will in the majority of instances meet with disappointment, and in order to effect a cure the besieging adhesions must sooner or later be reinforced by surgical aid and the diseased appendix removed. Indeed Dr. Cullingworth's statement about pelvic collections, "as one's experience increases the fewer become the number of incomplete operations," ought to apply with equal if not greater force to such an acute deadly disease as appendicitis.

In a previous paper I gave details of a case in which I thought the patient had recovered from an attack and was on the point of discharging him from the hospital, as he had no signs or symptoms left of any infective process in the appendical region. Taking into consideration the possibility of a recurrence at a distance of 300 miles (where he resided) from Buenos Ayres I advised him to have his appendix removed. At the operation I found nothing until I attempted to elevate the cæcum, which was adherent posteriorly. On exploration I discovered a tubular form of abscess tracking up behind the cæcum and ascending colon and a gangrenous perforated appendix. I confess this case gave my diagnostic sense a rude shock from which it has never recovered—I am happy to be able to state that the patient did.

The key to success in these purulent cases is to operate early and to introduce the sense of sight by a large incision, without the latter disaster is bound to occur. The method which I adopt is as follows. A four inch oblique incision (to begin with) is made over the centre of tumefaction, the external oblique is split parallel to its fibres and the underlying muscles are divided by a scalpel through the whole length of the wound. I found McBurney's gridiron method very unsatisfactory for it constantly happened that transverse muscular separation of the internal oblique and transversalis had to be supplemented by vertical incisions in order to gain sufficient room for manipulation and to see what one was doing. Also the barbarous practice of forcibly dragging muscles asunder by retractors opened up muscular planes which increased the risk of parietal infection during the evacuation of pus. For this reason I endeavour to disturb the muscles as little as possible and on opening the peritoneum hasten to insert silkworm gut sutures through the parietal wall on each side (as suggested by Mr A. Marmaduke Sheild) in order to avoid any muscular separation. These sutures are tied and the ends are grasped by pressure forceps which serve as excellent retractors or what is even better the ends may be sewn to the skin at some distance from each edge of the wound drawn taut and knotted, and in this manner they act as most convenient self retaining retractors. The pus having escaped the whole cavity is thoroughly mopped and brushed with large rolls of iodoform gauze. Then the hands are washed in a fresh solution of corrosive sublimate and alcohol (1 in 1000) and the towels are changed. Any adherent thickened omentum is first separated and excised, intestinal adhesions are next deliberately freed the field being kept dry on gauze pads. When the appendix is differentiated and brought to the surface an assistant grasps the appendical segment of the cæcum between the thumb and forefinger of each hand. His fingers act as efficient clamps and furthermore, steady the part while the appendix is looped off close to the cæcum by one stroke of the scissors and the little wound is closed by two rows of fine silk continuous sutures. After a final mopping of the whole field a large petticoat drain is inserted at the lower angle of the incision the end being placed at the most dependent point in the cavity the upper portion of the wound is closed by silkworm gut sutures, and a strip of iodoform gauze is passed down by a long blunt forceps to the bottom of the drainage-tube; a hole is made in the dressings so that the capillary drain may be changed by the nurse as often as may be necessary. I usually remove the tube on the third or fourth day substituting a small roll of iodoform gauze. A movement of the bowels is brought about on the second day which may be comfortably effected by one or two preparatory belladonna pills followed by an enema.

As to the treatment of ventral hernia, I should like to mention that I find that elliptical excision of the skin cicatrix and complete exposure and approximation of the muscular layers effect a cure. The important detail in the operation is not to leave a remnant of scar tissue in the depth of the wound, as fresh surface must be united to fresh surface in order to obtain a good result. Interrupted silkworm gut sutures passed methodically (by aid of pressure forceps applied to each layer) is the most satisfactory method of union.

With regard to fulminating appendicitis all surgeons are agreed as to the necessity for prompt intervention in this grave form of appendicitis and I very much regret that I am unable to report a single cure, as the six patients on whom I operated were practically moribund before admission to hospital. One feels at a loss how to explain the absence of adhesions in these cases. I think that rapidity and intensity of infection affording no time for their formation before perforation and the escape of fæcal matter takes place, is an inadequate explanation. A case which I operated on 18 months ago first raised my doubts on this point. A young man was attacked on a Thursday evening with severe pain in the right lower abdomen and vomited frequently during the night. On the following morning my friend Dr Dodds of Lomas was called in and diagnosed acute appendicitis and strongly urged immediate operation which was not acted on until the following Sunday when the patient was brought into the hospital. His temperature was then 104° F. his pulse was 120 and his tongue was very dry the abdomen was very much distended there were constant hiccough and absolute constipation no flatus or motion having passed since the onset—truly a poisoned state. I operated soon after admission and found the intestines very distended the appendix was gangrenous *without perforation* surrounded by a small quantity of turbid serum lying between the cæcum and the ileum no attempt at adhesion having taken place and the adjacent bowels presented a peculiar dusky dry appearance. On further exploration of the peritoneal cavity no flakes of lymph or pus were visible. I removed the appendix and provided free drainage. No reaction followed the bowels continued recalcitrant, and as a last resource I incised the cæcum on the second day. A little gas and fæcal matter escaped. Enterotomy proved useless the ileus continued, and he died on the following day. I had not known of Mr Sheild's suggestion at the time if I had I should certainly have injected magnesia directly into the cæcum through the appendical opening before suturing the latter.

It is possible that the absence of adhesions in this form of appendicitis may be explained by streptococcic infection causing intense toxæmia with destruction of the plastic elements in the blood. Possibly bacteriologists will soon be able to subdivide septicæmia into streptococcæmia and staphylococcæmia, the former being characterised by profound poisoning, little liquid, and no plasticity as in erysipelas and surgical scarlet fever, and the latter by less intense toxæmia, abundant pus, and adhesions In the majority of cases there is probably a mixed form of infection and the formation of adhesions may then depend on the streptococcus or staphylococcus being the predominant partner

As to the treatment of non purulent appendicitis I can only endorse what I advocated in my former paper, that owing to the impossibility of determining the exact pathological condition, and to the insidious nature of the disease, I consider it a duty to operate on every case within 24 hours after admission to the hospital, and the operation I perform differs from that employed in obvious purulent cases in that I commence with a two inch incision, which is promptly extended if the appendix cannot be brought easily to the surface Recently I have seen a case operated on in which the appendix was deeply adherent, and after one hour's poking with two fingers at the bottom of a small dark hole the surgeon succeeded in breaking off the top of the appendix, which afterwards could not be discovered even with the aid of head lights Such a procedure is really more dangerous than the disease itself The appendix is next carefully ligated and although the vessels may be of small calibre they deserve serious attention I operated on a most simple case about a year ago, and five days later had to re open and to enlarge the wound in order to clear out a huge mass of blood clot which occupied the greater part of the right abdomen the result of hæmorrhage coming from a small vessel in the meso appendix which had escaped ligation The patient recovered. Having ligated and separated the mesentery from the appendix a circular incision is made around the latter close to the cæcum, which exposes the mucous coat, this is ligated with fine silk Pressure forceps are then applied to the distal portion of the appendix, about one-third of an inch from the ligature, the appendix is divided between and the stump is covered over by three or four Lembert sutures which take a firm grip of the cæcal wall I find that the pressure forceps prevent any leaking when the appendix is divided and no peritoneal soiling takes place. Some surgeons divide the appendix with a hot iron, quite oblivious of the fact that the formation of eschars, even within the forgiving peritoneum, is inconsistent with modern ideas as to the healing and treatment of wounds

In all recent surgical text-books one sees illustrations of what is usually described as the "cuff" operation, in this the peritoneal coat is circularly divided and dissected down towarded the cæcum. The mucous coat is then ligated with silk, the appendix is divided, and the above mentioned web of serous membrane is drawn over the stump by sutures The advocates of this finicking procedure evidently have not studied the late Mr Greig Smith's definition of a good intestinal suture (See the diagram, Fig 129, "Abdominal Surgery," illustrating the best and the worst methods) As he stated "Halsted first pointed out the importance of catching up a few fibres of the submucosa to give holding power to the suture, to pick up many fibres by pushing the needle along the line of fibrous layer gives greatly increased firmness to the suture grip The muscular and peritoneal coats are easily torn through the fibrous coat is not easily torn " The parts are finally thoroughly dried with gauze pads and the external wound is united by interrupted silkworm gut sutures, which are usually removed from the seventh to the tenth day and the patients are discharged at the end of the third week. In conclusion I should like to add that in this series of 140 cases 63 were purulent, in all I had nine deaths, six of which occurred in fulminating cases, as stated before, and I venture to think that a mortality of 2·2 per cent. in the remaining 134 operations compares favourably with the results of any other form of treatment

Buenos Ayres

A CASE OF RUPTURED GLUTEAL ANEURYSM, TRANSPERITONEAL LIGATURE OF THE INTERNAL ILIAC ARTERY

BY HERBERT W PAGE, M C CANTAB, F R C S ENG,

SENIOR SURGEON TO ST MARY'S HOSPITAL, LONDON, PRESIDENT OF THE NEUROLOGICAL SOCIETY

THE rupture of an aneurysm is always a grave incident in surgery The rupture of a gluteal aneurysm can never fail to be of interest to surgeons because of the classical case of the great Syme who by a memorable example pointed out for all time the way to deal with it. Circumstances may, however, at any moment render it impossible in the course of an operation for turning out the clot to rest content with applying a ligature to the bleeding gluteal artery even though the bleeding may be stayed thereby, and the surgeon may find it imperative to proceed at once to tie the feeding trunk of the internal iliac artery Such was the state of things in the case which I desire here to place on record

A man, aged 44 years, but looking many years older, wasted, anæmic, and ill with a history of rheumatic fever in childhood and with physical evidences of cardiac and vascular disease, a coachman by occupation, was admitted to St. Mary's Hospital on Feb 23rd, 1902. At the beginning of his illness five weeks before admission he had suffered some pain in the course of the right sciatic nerve with tingling in his toes, but he had no pain now He had not been ill recently nor had he met with an accident, but one day on getting down from his box he had noticed a swelling in the right buttock. This swelling had steadily increased so that on admission it was of huge size, reaching from the crest of the ilium to below the great trochanter It was fluctuant and non pulsatile, while towards its lower end it became dusky in colour, and immediately above the trochanter there was some inflammatory redness Believing that it might possibly be an abscess, with which ready made diagnosis the man had been sent to the hospital, my house surgeon, Mr A. Whitmore, made a small inch-long exploratory incision a couple of inches above the great trochanter, where the skin was red, but finding nothing except blood clot immediately closed the wound. He acted, indeed, with excellent judgment. Per rectum it was thought that some swelling could be felt high up on the right side of the pelvis and that a vessel was beating over it. Personally, I was unable to satisfy myself of the accuracy of this observation. Abscess being excluded by the exploratory incision, the diagnosis clearly lay between ruptured aneurysm, simple hæmatoma owning no known cause, and new growth So markedly fluctuant, however, was the swelling that new growth seemed to be out of the question, and the belief was held that we should in all probability have to deal with a ruptured gluteal aneurysm, and preparations for meeting any difficulty which might arise in the course of operation were made accordingly This was undertaken on Feb 25th, my colleague, Mr Silcock, very kindly helping me

The original exploratory incision was first laid open and then gradually enlarged in the upward direction With a spoon and a stream of sterile water more than two pints of old and recent blood-clot were rapidly evacuated, and so vast was the cavity that of necessity the incision was by degrees extended from the crest of the ilium to below the great trochanter From the depths of the cavity laminated clot was turned out, one large portion being spherical in form, and looking much as if it had at one time been part of an aneurysmal sac Deeper clots and laminated fibrin being detached it was now for the first time obvious that active hæmorrhage was taking place from the sciatic notch This was controlled by sponge pressure until all clot had been quickly removed and we were then able to see that blood came in spurts from within the sciatic notch, evidently from the gluteal artery itself. Happily, this bleeding was under complete control by the finger but the actual bleeding point could not be seen, and evidently lay deeply on the inner side of the bone After several unsuccessful attempts to seize the bleeding point with pressure forceps, Mr Silcock ultimately made a luckly hit with a pair of forceps bent at the end to a right angle and completely stopped the bleeding It seemed to us both, however, that no reliance could be placed on these forceps for the *permanent* arrest of hæmorrhage, especially as the very awkward projection of the handles of the forceps from the wound made it impossible to secure them in such a manner as to be perfectly safe in the various unavoidable movements of the patient His condition allowing it, it was therefore resolved to tie the internal iliac artery at once. With the man still lying on his side the abdomen was opened in the right semilunar line, a position which favoured the fall of the intestines out of the way towards the left. Exceeding thinness of the abdominal wall was, moreover helpful in making the discovery of the vessel comparatively easy The covering peritoneum having been incised a single ligature of small silk was applied in the usual way This transperitoneal ligature of the internal iliac artery had not indeed added much to the length of the operation and the condition of the patient when he left the table was exceedingly good, this being due of course, in no small measure to the efficient way in which the bleeding had been controlled. He rallied well and for three days gave promise of recovery His temperature then suddenly rose to 103° F pneumonia set in and from this he died on March 2nd. Whether this was in any degree the result of septicity in the wound I cannot say but it is quite certain that perfect asepsis was not maintained and perhaps in all the circumstances—the size and depth of the cavity and the great probability that the parts were septically inflamed before the operation—this is no matter for surprise. Nevertheless, it is deeply to be regretted because there had been no return of bleeding and at the necropsy the internal iliac artery from the site of ligature onwards into the gluteal artery itself was found firmly occluded by healthy clot. The peritoneal and abdominal wounds were soundly healed There was grey hepatisation of the lower lobe of the right lung with extensive vegetations on the mitral and aortic valves.

The point of chief interest in this case is the necessity which arose in the course of the usual operation of turning out the blood-clot and aneurysmal remains of ligaturing the main trunk from which the diseased gluteal vessel sprang In more accessible parts this would hardly have called for comment but in the case of the gluteal artery the surgeon cannot lose sight of the fact that the opening in the vessel may perchance be intra pelvic and the application of a ligature impossible It was a happy chance and nothing else that the bleeding point was in this instance secured by bent forceps on the inner side of the bone. Had we failed to secure it in this manner it would have been a matter of exceeding difficulty if not impossibility to stay the bleeding and the patient might have bled to death before the iliac artery could have been tied I do not know how such a state of things could be foretold before the ruptured sac was laid open and the clots were turned out, and it is a question whether in the case of ruptured gluteal aneurysm it would not be good practice to secure the internal iliac artery before proceeding to deal with the aneurysm itself Here it is that transperitoneal ligature comes to the surgeon's aid, for in comparison with the old method of reaching the vessel this procedure is easy of execution and without much risk And if such a step involves departure from the principles which hold good in dealing with ruptured aneurysm it is surely justified by the anatomical arrangement of the vessels in this region of the body and absolves the surgeon from the necessity of following a law which may be here inapplicable and of no avail.

ON THE PRECIPITIN OF COBRA VENOM A MEANS OF DISTINGUISHING BETWEEN THE PROTEIDS OF DIFFERENT SNAKE POISONS

BY GEORGE LAMB, M B, GLASG

CAPTAIN INDIAN MEDICAL SERVICE

(*From the Research Laboratory Bombay*)

PRELIMINARY ACCOUNT

SINCE Bordet[1] in 1899 first demonstrated that the serum of a rabbit which was treated by intra peritoneal injections of the serum of another species of animal acquired after a time the property of forming a coagulum or precipitum when mixed with the serum of an animal of the same species this phenomenon has been worked out by other observers[2] for the sera of many species of animals and for various other proteid substances. It is not my intention in this note to trace in detail the evolution of the subject up to the present day It will suffice to mention that specific precipitins have been prepared for the sera of many species of animals and for such proteid substances as casein of milk the albumin which occurs pathologically in urine crystallised egg albumin, pure serum globulin from the sheep and from the bullock and Witte's peptone. The research made with the precipitins of the latter four of these substances was among the last published works of the late Dr Walter Myers In a paper in THE LANCET[3] he showed that the precipitin prepared by injections of egg albumin had no action on the other proteids with which he worked—namely serum globulin from the sheep, serum globulin from the bullock and Witte's peptone. He found however that the precipitin of serum globulin from the sheep did form a slight coagulum with the globulin got from bullock's serum and that, *vice versâ* the precipitin prepared with bullock's serum globulin precipitated to a slight degree the globulin got from sheep's serum Myers also demonstrated that the precipitins are used up in the course of their action. He looked upon this fact as strong evidence that the action of these bodies is a chemical action

It would appear then from these observations that we had at hand a means of distinguishing between various proteids and mixture of proteids for there can be no doubt that this animal test is more delicate than any chemical method of discrimination at present available. Up to within a few months ago all workers on the precipitins of immune sera looked upon this reaction as practically a specific one Thus for example it was thought that a precipitin prepared with human serum, while forming a slight precipitum with monkey's serum especially with the serum of the anthropoid apes gave absolutely no reaction with the sera of other animals more distantly related to man and that the same law held good for the precipitin of horse's serum when tested with the serum of the ass and of fowl's serum when tested with the serum of the pigeon &c

Quite recently however two French observers, Linossier and Lemoine,[4] have published a summary of their researches with the precipitins prepared for the sera of several species of animals. In a series of most interesting papers these workers have shown that the precipitins for proteid substances in general are not absolutely specific to any one chemical form of proteid and further, that the precipitin prepared for the serum of one species of animal is not absolutely specific for the serum of that species or even of allied species. Thus they found that a precipitin prepared by injections of the serum of an animal precipitates also the proteids in the saliva, in the semen, in the milk, and in the muscle juice of the same species of animal and also that such a serum precipitin causes a certain amount of precipitation with sera of other species of animals But they showed that while the reaction is not absolutely specific a marked degree of specificity is demonstrable inasmuch as the precipitum obtained is less voluminous as the animal the serum of which is being tested is separated in the animal scale from the animal the blood of which was used for the preparation of the precipitin They have shown in short, that there is in this phenomenon a marked relative specificity This relative specificity is apparent from the following two facts (1) the minimum quantity of precipitin necessary to give a precipitum is much less in the case of the corresponding serum than in the case of other sera and (2) the precipitum obtained is much more voluminous with the corresponding serum than with other sera. Further these workers found that in order to give a numerical expression to this relative specificity it is only necessary to ascertain at what maximum dilution the different sera begin to be precipitated under the action of a known precipitin the proportion of precipitin to diluted serum remaining the same in all the preparations Thus working with a serum prepared with the blood of the ox they found that the precipitin obtained began to cause a precipitation when mixed with the following sera at the maximum dilutions of serum of ox 1 in 5000 serum of horse, 1 in 300 and serum of man 1 in 50 It follows then, that in order to demonstrate the specificity of proteid precipitin the proteid which is being experimented with must be greatly diluted before an exact and trustworthy result can be obtained In the case of sera these observers advocate that to get a specific reaction the serum to be tested should be diluted at least a thousand fold. They show further that the test is so delicate that 0 01 milligramme of the proteid used for preparing the precipitin can be easily detected if a suitable amount of precipitin is brought in contact with this quantity [illegible]

[4] Comptes Rendus de la Société de Biologie Tome [illegible] 1902, pp 25, 278, 320 and 1[illegible]

however, evident for *a priori* reasons that the quantity of precipitin in a sample of immune serum must vary according to the degree of immunity obtained by the injections, it is unnecessary here to enter into the figures detailed by these observers of the amount of serum which they consider necessary completely to precipitate a given quantity of proteid and of the amount of proteid which can use up completely the total quantity of precipitin in a sample of immune serum.

Such, then, are the general principles upon which the specificity of this reaction depends. And while these two French workers hold that the reaction is not absolutely specific they consider that it is quite trustworthy as a means of distinguishing proteid substances from one another if strict attention is paid to the details of technique roughly outlined above. We shall see later, from the observations which I have to put on record, that these principles are well founded.

With this introduction I may now pass on to put forward the results which I have obtained, working with an immune serum prepared for pure cobra venom. For the preparation of this serum rabbits were the animals employed. The rabbits the sera of which I used in the experiments about to be detailed were treated with subcutaneous injections of pure unheated cobra venom over a period of from four to five months, the injections being made at intervals of about 10 days. At the time of my observations they were able to stand a quantity a little over four times the minimum lethal dose of venom. For the demonstration and measurement of the precipitation action of the serum on the solution of poison the sedimentation tubes and the technique devised by Professor A. E. Wright[5] of Netley were employed. The advantages of using these tubes, as against small test tubes, I found to be very great. By their means exact measurements and dilutions, either of serum or of venom solution, can be accurately accomplished; only a small quantity of serum is necessary; the resulting precipitum, when present, is easily seen; further, after the precipitum has completely settled at the bottom of the tube the clear supernatant fluid is easily obtained by merely filing off the end of the tube containing the precipitum. The tubes, however, should be of slightly greater diameter than those recommended by Wright for serum diagnosis. It may be noted in passing that the precipitum obtained with cobra venom is indistinguishable, both macroscopically and microscopically, from the bacterial deposit obtained when the organisms of typhoid and Malta fevers are agglutinated and sedimented under the action of their specific sera. There was no doubt of the purity of the snake venoms with which I worked. With the exception of the poison of *Hoplocephalus curtus*, for which I am indebted to the kindness of Dr. F. Tidswell of Sydney, these were all collected, carefully dried, and stored under my own supervision. This precaution seems to me to be necessary, for a perusal of the literature of snake venoms shows one the great importance of working with pure venoms and of carefully differentiating the poison of one species from that of another even when the species are closely allied. I have pointed out in previous papers that no conclusions as to the physiological action of any one kind of venom can be drawn from the investigation of the action of the venom of even a closely allied species.

We shall first consider, then, the action which a serum prepared in the manner which I have indicated has on cobra venom itself, and then pass on to see its effect when mixed in the same way with a few other varieties of snake poison. As a preliminary measure, however, it was necessary to ascertain if normal rabbit's serum contained any precipitin for cobra venom. I experimented with the sera of six normal rabbits, mixing these in two different proportions—namely, four parts to one part—and in equal parts with solutions of cobra venom of four different strengths—namely, 1 per cent., 0·1 per cent., 0·01 per cent., and 0·001 per cent. In practically all the tubes which were filled in with one part of 1 per cent. venom and four parts of serum either a trace of or a marked precipitum was obtained after 24 hours; in a few instances in which the serum and the 1 per cent. venom solution were mixed in equal proportions a mere trace of precipitum was observed. On the other hand, in not a single instance in which the weaker strengths of venom solution—namely, 0·1 per cent., 0·01 per cent., and 0·001 per cent.—were employed was any precipitum found after the tubes had stood for 24 hours. It would appear, then, that normal rabbit's serum contains a trace of a substance capable of causing a precipitum with the proteids of cobra venom, but that the presence of this substance is only demonstrable when the solution of poison used is a comparatively strong one. It is evident, therefore, that in order to demonstrate the specific precipitin which, as we shall see, makes its appearance in considerable quantity in the blood as a result of repeated injections of cobra venom it is essential to use comparatively weak solutions of the poison. With the sera with which I worked it is also essential, as we shall see, to use an excess of serum in order to get the best results.

Working in this way and employing, as I have said, Wright's sedimentation tubes for the purpose of measuring the proportions of serum and venom solution and for the purpose of appraising the result of the reaction, one observes a copious and well marked precipitum when the serum of an immunised rabbit is brought in contact with a solution of cobra venom. A reference to Table I. of the protocols will show the result when solutions of cobra venom of strengths of 0·1 per cent., 0·01 per cent., 0·001 per cent., and 0·0001 per cent. respectively were mixed in varying proportions with cobra venom serum. In this table, also, for the sake of a comparison to be referred to later, the result of the similar reaction got with daboia venom and the same serum is included. Confining our attention, however, for the present to the precipitation reaction which this serum gives with cobra venom, it is evident from a study of the table that in order best to demonstrate this action an excess of such an immune serum as the one with which I worked should be added to a comparatively, but not too, weak solution of venom. Thus in those preparations in which two, three, or four parts of serum were mixed with one part of 0·1 per cent. and 0·01 per cent. solutions of venom a copious precipitum was obtained. When, however, the proportion of serum to venom solution was gradually decreased the precipitum became less and less and ultimately none was formed. With the weaker solution of venom—namely, 0·001 per cent., only a slight precipitum was obtained and that only when the serum was less in quantity than the venom solution. Finally, with the very weak solution of venom—namely, 0·0001 per cent.—no precipitum was formed at all.

Before proceeding to attempt to give a numerical expression of the amount of precipitin in the serum which was used for these experiments I have to draw attention to two facts of importance: (1) that the serum is active for those proteids in cobra venom which are incoagulable by heat, and (2) that heating the serum to a moderate degree does not affect the action of the precipitin. To demonstrate this first fact a 0·2 per cent. solution of cobra venom was divided into two portions, one portion was left unheated while the other portion was heated in a water bath at 75° C. for half an hour. The proteids coagulated in this way were then removed by filtration. The serum of a rabbit immunised with cobra venom was then mixed in different proportions with each of these two solutions after the manner which I have already described. The results of these experiments are detailed in Table II. of the protocols. From this table it will be seen that no difference was noticed between the precipita obtained with the filtrates containing the incoagulable proteids of the venom and the precipitate got with the solutions of the whole poison. As a like result was obtained with daboia venom, and for the sake of convenience and comparison, a similar series of experiments with this venom is detailed in this table. This will be referred to later. To demonstrate the second fact which I have stated above—namely, that heating to a moderate degree does not affect the precipitin of cobra venom—serum of a rabbit which had been treated with repeated injections of cobra venom was divided into two portions, one portion was left unheated while the other portion was heated in a water bath at 55° C. for half an hour. The precipitation reaction of these two samples of serum was then tested side by side with a 0·1 per cent. solution of cobra venom. This series of experiments is detailed in Table III. of the protocols. From this table it will be seen that no difference was apparent between the preparations made with unheated serum and those made with heated serum. In this table also, for the sake of convenience, similar observations with the same sample of serum and daboia venom are included. Reference will be made to these observations later.

I have stated above that Myers found that the precipitins with which he worked were used up in the course of their action and that he looked upon this fact as strong evidence that the action of these bodies is a chemical action. I have found also that the precipitin of cobra venom is completely used in the course of its action and that by estimating with what proportions of serum and venom solution of known strength this occurred a numerical expression could be given to the precipitation value of the serum. Thus, if a suitable proportion of serum and venom solution be mixed and left in contact for from 18 to 24 hours so that a copious precipitum settles down to the bottom of the tube it is found that the clear supernatant fluid contains neither precipitin nor precipitable proteid I found that with the serum of the rabbit with which I worked this complete neutralisation took place when six parts of serum were brought in contact with one part of a 0·05 per cent. solution of poison A reference to Tables IV (*a*) and (*b*) of the protocols will show the method by which this fact was experimentally demonstrated. From these tables it will also be seen that when the serum was present in greater amount than six parts to one part of venom solution (0·05 per cent.) the supernatant fluid contained free precipitin, the quantity of this free precipitin depending on the amount of serum used, and *vice versâ* when the serum was present in less amount than six parts to one part of the poison solution (0·05 per cent.) the supernatant fluid contained free precipitable substances which were precipitated on the addition of fresh serum. If we take it, then, that six parts of serum were exactly neutralised by one part of a solution of venom of 0·05 per cent. strength a simple calculation will show that 1 cubic centimetre of this serum—namely the immune serum which I used in this experiment—would be neutralised by 0·083 milligramme of cobra venom as far as the precipitin was concerned. Until however I have obtained a serum for cobra venom of much greater antitoxic power than this serum I am unable to experiment with the view of ascertaining whether the precipitin value, estimated [illegible] following will serve as a method of standardising the [illegible] therapeutic purposes. Should this method be avail. [illegible] it seems to me that we shall have at hand a method of standardisation much simpler easier to put into practice and more exact than any method in which animal's lives are used as the index of the neutralisation point For instead of depending on a variable element—namely an animal's personal idiosyncrasy to the poison—we shall have as our basis of observation a chemical reaction the result of which can be easily seen by the naked eye Many more experiments, however will have to be undertaken before any definite conclusions on this point can be arrived at.

---

[5] THE LANCET, July 5th, 1902, p. 11. Brit. Med. Jour., Feb. 5th, 1898.

From this brief preliminary account of the precipitin of the proteids of cobra venom it is evident that this reaction is of the same nature as the specific serum reaction to which I have referred above, and also strictly analogous to the reaction which Myers[6] described with the precipitins of white of egg and serum globulins.

We have now in conclusion, to pass on and to show how this reaction can be used as a means of differentiating the proteids of one kind of snake venom from the proteids of any other variety Up to now I have had at my disposal only the serum of animals immunised with cobra venom, I hope, at a later date, to extend these observations, using sera prepared with several other kinds of snake poison I have tested this cobra venom serum with four other snake venoms—namely (1) with the venom of *Daboia Russellii* the Indian chain viper (2) with the venom of *Echis carinata* or phoorsa, a small Indian viper (3) with the venom of *Bungarus fasciatus* or banded krait, an Indian snake of the colubrine family, and (4) with the venom of *Hoplocephalus curtus* the Australian tiger snake, also a colubrine snake. I have already incidentally drawn attention to the action of cobra venom precipitin on the first mentioned of these poisons. We shall consider immediately the results of the whole of these observations.

The technique which was used in these experiments was slightly varied from that which I have already described This variation consisted in bringing the same proportions of serum and venom solutions of different strengths in contact with one another the observation of the result being as in the other experiments, appraised in Wright's tubes 18 to 24 hours after the preparations were put up. In one series of experiments three parts of serum and in a second series two *parts of serum were mixed with one part of venom solution*, which varied in strength from 0·1 per cent to 0·001 per cent. The results of these two series of observations are recorded in Tables IV and V of the protocols respectively As a control and for the sake of comparison with the daboia venom series, a similar series of observations with the same sample of serum and cobra venom the poison which was used in the preparation of the serum is included in each of these tables A glance at these tables will show that the precipitin which is developed in the animal body as a result of injections of pure cobra venom has no reaction on three of the poisons with which I experimented—namely (1) the venom of *Echis carinata* (2) the venom of *Bungarus fasciatus*, and (3) the venom of *Hoplocephalus curtus* Two of the snakes—viz., *Bungarus fasciatus* and *Hoplocephalus curtus*—are colubrine snakes while *Echis carinata* is a viper Without entering at present into the consideration of the physiological action of these venoms compared with the action of cobra poison—a question which I shall take up in another communication—we can at once say from this precipitin test that the proteids which these three venoms contain have not the same chemical composition as the proteids of cobra venom. We have here, then, another example of the extreme delicacy of this biological test for proteids when compared with the crude methods of discrimination which have been available to physiological chemists up to the present day This result further completely disproves Martin's[7] hypotheses—namely that at least two proteid substances are present in all snake venoms (1) a proteid substance which is coagulable by heat and which exerts its physiological action on the blood and heart and (2) one which is incoagulable by heat and which kills by causing paralysis of the central nervous system and that snake venoms only differ from one another in physiological action according as they contain mo[illegible] less of one or other of these proteids—for the observ[illegible] which I have just recorded definitely prove th[illegible] on[illegible] these three kinds of poison contains any of the pro[illegible]stances which are present in cobra venom.

Let [illegible] on, finally to notice the reaction given with daboia venom and cobra venom serum. The problem which arises out of the fact that the serum prepared with cobra venom forms a coagulum with daboia venom as well as with its corresponding poison is a problem which will require careful investigation. I do not, therefore, intend in the present note to go into this question beyond drawing attention to one or two points which suggest themselves from the data contained in the various tables of the protocols. A reference to Table I of the protocols will show that when a 0·1 per cent. solution of both cobra and daboia venoms was used no difference was noticed in the precipitation reaction when varying amounts of the immune serum and of the venom solutions were brought in contact. Such a result would appear to warrant the *conclusion that the proteids of* cobra and daboia venoms were chemically identical. Now in a recent paper[8] along with Dr W Hanna, and in a paper which is in process of publication, I have definitely shown that the physiological action of cobra venom is quite different from the physiological action of daboia venom I have shown that even the actions which these two venoms have on the red blood cells and on the coagulability of the blood plasma, which at first sight appeared of the same nature, can be shown on closer investigation to be quite distinct. It is also important in this connexion to point out, as was shown by Hanna and myself[9] that Calmette's antivenomous serum does neutralise cobra venom but has no effect on daboia poison. If then, this biological test should show on further investigation that the proteid constituents of cobra venom are exactly the same as those of daboia venom we must conclude that the proteids contained in these venoms are not the toxic constituents of the poisons. The results tabulated in Tables II and III go to support this hypothetical conclusion for a glance at these two tables will show (1) that cobra venom serum forms a precipitum with the proteids of daboia venom which are incoagulable by heat, exactly the same as the precipitum given with the proteids of cobra venom which are incoagulable by heat and (2) that heated cobra venom serum forms a precipitum with daboia venom in every way the same as that formed with however, evident for *a priori* reasons that the quantity of precipitin in a sample of immune serum must vary according to the degree of immunity obtained by the injections, it is unnecessary here to enter into the figures detailed by these observers of the amount of serum which they consider necessary completely to precipitate a given quantity of proteid and of the amount of proteid which can use up completely the total quantity of precipitin in a sample of immune serum.

Such then, are the general principles upon which the specificity of this reaction depends. And while these two French workers hold that the reaction is not absolutely specific they consider that it is quite trustworthy as a means of distinguishing proteid substances from one another if strict attention is paid to the details of technique roughly outlined above. We shall see later, from the observations which I have to put on record, that these principles are well founded.

With this introduction I may now pass on to put forward the results which I have obtained, working with an immune serum prepared for pure cobra venom. For the preparation of this serum rabbits were the animals employed. The rabbits the sera of which I used in the experiments about to be detailed were treated with subcutaneous injections of pure unheated cobra venom over a period of from four to five months, the injections being made at intervals of about 10 days. At the time of my observations they were able to stand a quantity a little over four times the minimum lethal dose of venom. For the demonstration and measurement of the precipitation action of the serum on the solution of poison the sedimentation tubes and the technique devised by Professor A. E. Wright[5] of Netley were employed. The advantages of using these tubes, as against small test tubes, I found to be very great. By their means exact measurements and dilutions, either of serum or of venom solution, can be accurately accomplished ; only a small quantity of serum is necessary ; the resulting precipitum, when present, is easily seen ; further, after the precipitum has completely settled at the bottom of the tube the clear supernatant fluid is easily obtained by merely filing off the end of the tube containing the precipitum. The tubes, however, should be of slightly greater diameter than those recommended by Wright for serum diagnosis. It may be noted in passing that the precipitum obtained with cobra venom is indistinguishable, both macroscopically and microscopically from the bacterial deposit obtained when the organisms of typhoid and Malta fevers are agglutinated and sedimented under the action of their specific sera. There was no doubt of the purity of the snake venoms with which I worked. With the exception of the poison of *Hoplocephalus curtus*, for which I am indebted to the kindness of Dr F Tidswell of Sydney, these were all collected, carefully dried, and stored under my own supervision. This precaution seems to me to be necessary, for a perusal of the literature of snake venoms shows one the great importance of working with pure venoms and of carefully differentiating the poison of one species from that of another even when the species are closely allied. I have pointed out in previous papers that no conclusions as to the physiological action of any one kind of venom can be drawn from the investigation of the action of the venom of even a closely allied species.

We shall first consider, then, the action which a serum prepared in the manner which I have indicated has on cobra venom itself, and then pass on to see its effect when mixed in the same way with a few other varieties of snake poison. As a preliminary measure, however, it was necessary to ascertain if normal rabbit's serum contained any precipitin for cobra venom. I experimented with the sera of six normal rabbits, mixing these in two different proportions—namely four parts to one part—and in equal parts with solutions of cobra venom of four different strengths—namely, 1 per cent , 0·1 per cent , 0·01 per cent., and 0·001 per cent. In practically all the tubes which were filled in with one part of 1 per cent venom and four parts of serum either a trace of or a marked precipitum was obtained after 24 hours ; in a few instances in which the serum and the 1 per cent venom solution were mixed in equal proportions a mere trace of precipitum was observed. On the other hand, in not a single instance in which the weaker strengths of venom solution—namely, 0·1 per cent 0·01 per cent , and 0·001 per cent —were employed was any precipitum found after the tubes had stood for 24 hours. It would appear, then, that normal rabbit's serum contains a trace of a substance capable of causing a precipitum with the proteids of cobra venom, but that the presence of this substance is only demonstrable when the solution of poison used is a comparatively strong one. It is evident, therefore, that in order to demonstrate the specific precipitin which, as we shall see, makes its appearance in considerable quantity in the blood as a result of repeated injections of cobra venom it is essential to use comparatively weak solutions of the poison. With the sera with which I worked it is also essential, as we shall see, to use an excess of serum in order to get the best results.

Working in this way and employing, as I have said, Wright's sedimentation tubes for the purpose of measuring the proportions of serum and venom solution and for the purpose of appraising the result of the reaction, one observes a copious and well marked precipitum when the serum of an immunised rabbit is brought in contact with a solution of cobra venom. A reference to Table I of the protocols will show the result when solutions of cobra venom of strengths of 0·1 per cent., 0·01 per cent , 0·001 per cent., and 0·0001 per cent. respectively were mixed in varying proportions with cobra venom serum. In this table, also, for the sake of a comparison to be referred to later, the result of the similar reaction got with daboia venom and the same serum is included. Confining our attention, however, for the present to the precipitation reaction which this serum gives with cobra venom, it is evident from a study of the table that in order best to demonstrate this action an excess of such an immune serum as the one with which I worked should be added to a comparatively, but not too, weak solution of venom. Thus in those preparations in which two, three, or four parts of serum were mixed with one part of 0·1 per cent. and 0·01 per cent. solutions of venom a copious precipitum was obtained. When, however, the proportion of serum to venom solution was gradually decreased the precipitum became less and less and ultimately none was formed. With the weaker solution of venom—namely, 0·001 per cent., only a slight precipitum was obtained and that only when the serum was less in quantity than the venom solution. Finally, with the very weak solution of venom—namely, 0·0001 per cent.—no precipitum was formed at all.

Before proceeding to attempt to give a numerical expression of the amount of precipitin in the serum which was used for these experiments I have to draw attention to two facts of importance (1) that the serum is active for those proteids in cobra venom which are incoagulable by heat, and (2) that heating the serum to a moderate degree does not affect the action of the precipitin. To demonstrate this first fact a 0·2 per cent solution of cobra venom was divided into two portions ; one portion was left unheated while the other portion was heated in a water bath at 75° C for half an hour. The proteids coagulated in this way were then removed by filtration. The serum of a rabbit immunised with cobra venom was then mixed in different proportions with each of these two solutions after the manner which I have already described. The results of these experiments are detailed in Table II of the protocols. From this table it will be seen that no difference was noticed between the precipita obtained with the filtrates containing the incoagulable proteids of the venom and the precipitate got with the solutions of the whole poison. As a like result was obtained with daboia venom, and for the sake of convenience and comparison, a similar series of experiments with this venom is detailed in this table. This will be referred to later. To demonstrate the second fact which I have stated above—namely, that heating to a moderate degree does not affect the precipitin of cobra venom—serum of a rabbit which had been treated with repeated injections of cobra venom was divided into two portions ; one portion was left unheated while the other portion was heated in a water bath at 55° C for half an hour. The precipitation reaction of these two samples of serum was then tested side by side with a 0·1 per cent. solution of cobra venom. This series of experiments is detailed in Table III of the protocols. From this table it will be seen that no difference was apparent between the preparations made with unheated serum and those made with heated serum. In this table also, for the sake of convenience, similar observations with the same sample of serum and daboia venom are included. Reference will be made to these observations later.

I have stated above that Myers found that the precipitins with which he worked were used up in the course of their action and that he looked upon this fact as strong evidence that the action of these bodies is a chemical action. I have found also that the precipitin of cobra venom is completely used in the course of its action and that by estimating with what proportions of serum and venom solution of known strength this occurred a numerical expression could be given to the precipitation value of the serum. Thus, if a suitable proportion of serum and venom solution be mixed and left in contact for from 18 to 24 hours so that a copious precipitum settles down to the bottom of the tube, it is found that the clear supernatant fluid contains neither precipitin nor precipitable proteid I found that with the serum of the rabbit with which I worked this complete neutralisation took place when six parts of serum were brought in contact with one part of a 0·05 per cent. solution of poison A reference to Tables IV (*a*) and (*b*) of the protocols will show the method by which this fact was experimentally demonstrated. From these tables it will also be seen that when the serum was present in greater amount than six parts to one part of venom solution (0·05 per cent.) the supernatant fluid contained free precipitin, the quantity of this free precipitin depending on the amount of serum used and *vice versâ* when the serum was present in less amount than six parts to one part of the poison solution (0·05 per cent.) the supernatant fluid contained free precipitable substances which were precipitated on the addition of fresh serum. If we take it, then, that six parts of serum were exactly neutralised by one part of a solution of venom of 0·05 per cent. strength, a simple calculation will show that 1 cubic centimetre of this serum—namely the immune serum which I used in this experiment—would be neutralised by 0·083 milligramme of cobra venom as far as the precipitin was concerned. Until however I have obtained a serum for cobra venom of much greater antitoxic power than this serum I am unable to experiment with the view of ascertaining whether the precipitin value, estimated following will serve as a method of standardising the therapeutic purposes. Should this method be avai seems to me that we shall have at hand a metho standardisation much simpler easier to put into practice more exact than any method in which animals lives used as the index of the neutralisation point. For ins of depending on a variable element—namely an ani personal idiosyncrasy to the poison—we shall have as basis of observation a chemical reaction the result of w can be easily seen by the naked eye Many more ex ments, however will have to be undertaken before definite conclusions on this point can be arrived at.

---

[5] THE LANCET July 5th, 1902, p 11 Brit Med Jour Feb 5th, 1898

From this brief preliminary account of the precipitin of the proteids of cobra venom it is evident that this reaction is of the same nature as the specific serum reaction to which I have referred above, and also strictly analogous to the reaction which Myers described with the precipitins of white of egg and serum globulins.

We have now in conclusion, to pass on and to show how this reaction can be used as a means of differentiating the proteids of one kind of snake venom from the proteids of any other variety Up to now I have had at my disposal only the serum of animals immunised with cobra venom I hope at a later date, to extend these observations using sera prepared with several other kinds of snake poison. I have tested this cobra venom serum with four other snake venoms—namely (1) with the venom of *Dabola Russellii* the Indian chain viper (2) with the venom of *Echis carinata* or fhoorsa, a small Indian viper (3) with the venom of *Bungarus fasciatus* or banded krait an Indian snake of the colubrine family and (4) with the venom of *Hoplocephalus curtus* the Australian tiger snake, also a colubrine snake. I have already incidentally drawn attention to the action of cobra venom precipitin on the first mentioned of these poisons. We shall consider immediately the results of the whole of these observations.

The technique which was used in these experiments was slightly varied from that which I have already described This variation consisted in bringing the same proportions of serum and venom solutions of different strengths in contact with one another the observations of the result being as in the other experiments, appraised in Wright's tubes 18 to 24 hours after the preparations were put up In one series of experiments three parts of serum and in a second series two parts of serum were mixed with one part of venom solution which varied in strength from 0·1 per cent to 0·001 per cent The results of these two series of observations are recorded in Tables IV and V of the protocols respectively As a control and for the sake of comparison with the dabola venom series, a similar series of observations with the same sample of serum and cobra venom the poison which was used in the preparation of the serum, is included in each of these tables A glance at these tables will show that the precipitin which is developed in the animal body as a result of injections of pure cobra venom has no reaction on three of the poisons with which I experimented—namely (1) the venom of *Echis carinata*, (2) the venom of *Bungarus fasciatus*, and (3) the venom of *Hoplocephalus curtus* Two of the snakes—viz. *Bungarus fasciatus* and *Hoplocephalus curtus*—are colubrine snakes, while *Echis carinata* is a viper Without entering at present into the consideration of the physiological action of these venoms compared with the action of cobra poison—a question which I shall take up in another communication—we can at once say from this precipitin test that the proteids which these three venoms contain have not the same chemical composition as the proteids of cobra venom. We have here, then another example of the extreme delicacy of this biological test for proteids when compared with the crude methods of discrimination which have been available to physiological chemists up to the present day This result further completely disproves Martin's[7] hypotheses—namely that at least two proteid substances are present in all snake venoms (1) a proteid substance which is coagulable by heat and which exerts its physiological action on the blood and heart and (2) one which is incoagulable by heat and which kills by causing paralysis of the central nervous system and that snake venoms only differ from one another in physiological action according as they contain mo less of one or other of these proteids—for the obser which I have just recorded definitely prove that no these three kinds of poison contains any of stances which are present in cobra venom

on, finally to notice the reaction given with and cobra venom serum. The problem which the fact that the serum prepared with cobra a coagulum with dabola venom as well as with ding poison, is a problem which will require estigation. I do not therefore intend in the te to go into this question beyond drawing atten one or two points which suggest themselves from the contained in the various tables of the protocols. A reference to Table I. of the protocols will show that when a 0·1 per cent. solution of both cobra and dabola venoms was used no difference was noticed in the precipitation reaction when varying amounts of the immune serum and of the venom solutions were brought in contact. Such a result would appear to warrant the conclusion that the proteids of cobra and dabola venoms were chemically identical. Now in a recent paper[8] along with Dr W Hanna, and in a paper which is in process of publication, I have definitely shown that the physiological action of cobra venom is quite different from the physiological action of dabola venom. I have shown that even the actions which these two venoms have on the red blood cells and on the coagulability of the blood plasma, which at first sight appeared of the same nature, can be shown on closer investigation to be quite distinct. It is also important in this connexion to point out, as was shown by Hanna and myself[9] that Calmette's anti venomous serum does neutralise cobra venom but has no effect on dabola poison If then, this biological test should show on further investigation that the proteid constituents of cobra venom are exactly the same as those of dabola venom we must conclude that the proteids contained in these venoms are not the toxic constituents of the poisons The results tabulated in Tables II and III. go to support this hypothetical conclusion for a glance at these two tables will show (1) that cobra venom serum forms a precipitum with the proteids of dabola venom which are incoagulable by heat, exactly the same as the precipitum given with the proteids of cobra venom which are incoagulable by heat and (2) that heated cobra venom serum forms a precipitum with dabola venom in every way the same as that formed with

[9] THE LANCET June 15th 1901 p. 1661 Journal of Pathology and Bacteriology 1902, vol viii. No 1 p. 1

cobra poison If, then, this test is a relatively specific test for proteids we have in all these data to which I have drawn attention evidence which suggests that the proteids of cobra venom are either identical with the proteids of daboia venom or failing this, that they possess the same "haptophoric group" It may be noted that if the former alternative were established it would follow that the proteid substances which are precipitated in these reactions are not the toxic elements of the venoms

On the other hand, when we come to look more closely into the results tabulated in Tables I. V, and VI., a slight difference is seen to exist between the reaction that the serum gave with cobra venom and that which it gave with daboia venom This difference consists in the fact that with the same amount of serum a precipitum is formed with a weaker solution of cobra venom than is the case when daboia venom is used This fact is shown best in the results detailed in Tables V and VI The difference certainly is not very great and it is just a question as to whether or not it is sufficient to warrant the conclusion that the proteids of the one poison are different from the proteids of the other venom so different (granting that these substances are the toxic constituents of the poisons) as to lead one to expect the physiological actions of the two venoms to be so distinct as they are I propose, however, to leave the problem in this position for the present, hoping that the experiments which are now in progress in this laboratory will settle the question one way or the other

PROTOCOLS

TABLE I —*Experiments to show the Precipitation Reaction of Cobra Venom Serum on Cobra Venom and on Daboia Venom*

The rabbit the serum of which was used for these experiments had received for over a period of four months repeated subcutaneous injections of pure acheated cobra venom At the time of these observations, the receiving about four times the minimum lethal dose further, ood we collected in the bent capsules figured by the bottom of allowed to clot and the clear serum was pipsily obtained two or three hours after withdrawal Four difftaining the of solutions of cobra and daboia venoms wereof slightly namely 0 1 per cent, 0 01 per cent., 0 001 pWright for 0 0001 per cent These were made with normg that the tion (0 75 per cent) The serum was brought inguishable, each venom solution in varying proportions as inacterial the table All dilutions, &c, were made by means of Malta sedimentation tubes in which also the mixtures were of for from 18 to 20 hours at laboratory temperature (about 29° C) after which time the observations were recorded In this and in all subsequent tables the following signs are used + signifies a copious precipitum, × signifies a marked precipitum, * signifies a slight or trace of precipitum, and 0 signifies no precipitum

Parts of serum	Parts of venom solution	Result							
		C V 1/	D V 1	C V 01/	D V 01/	C V ·001/	D V 001/	C V 0·01	D V 0001

1	10	0	0	*	0	0	0	0	0

TABLE II —*Experiments to Compare the Precipitation Reaction of Cobra Venom Serum with whole Cobra and Daboia Venoms and with the Same Poisons from which the Proteids Coagulable by Heat had been Removed*

The serum of the same rabbit as was used for the experiment detailed in Table I was employed A 0 2 per cent. solution of each poison was heated in a water bath for half an hour at 75° C The coagulated proteids were then removed by filtration The precipitation reaction of the serum with unheated and heated solutions of each venom was determined by a technique the same as I have already described

Parts of serum	Parts of venom solution	Results			
		C V unheated	C V heated	D V unheated	D V heated
4	1	+	+	+	+
3	1	+	+	+	+
2	1	+	+	+	+

1	10	0	0	0	0

TABLE IV (*a*) *and* (*b*) —*Experiments to Determine what Quantity of Cobra Venom Serum was required exactly to Neutralise and Precipitate a Given Quantity of Cobra Venom*

The serum used was got from a rabbit which had received repeated doses of pure cobra venom for over a period of four months The strength of venom solution employed was 0 05 per cent Two series of experiments were made.

In the first series varying proportions of serum were mixed with one part of the venom solution The preparations were allowed to stand at laboratory temperature (about 29° C) for 24 hours The following was the result obtained

Parts of serum	Parts of venom solution	Result
16	1	+
14	1	+
12	1	+
8	1	+
6	1	+
4	1	+
2	1	×
1	1	×
½	1	*

In the second series of experiments the clear supernatant fluid in each of these tubes was got by simply filing off the end of the tube with the contained precipitum The supernatant fluid was divided into two portions To one portion was added an equal quantity of cobra venom solution (0·05 per cent.) and to the other portion there was added an equal

---

[10] Brit Med Jour Feb 5th 1898.

amount of the same cobra venom serum as was used in the first series. The mixtures were stored in Wright's tubes. The result was observed from 20 to 24 hours after the preparations had been put up. It was as follows —

Proportion of serum to venom solution in original preparation	C V (0·05 per cent.)	Serum
16-1	×	0
14-1	×	0
12-1	*	0
8-1	*	0
6-1	0	0
4-1	0	*
2 1	0	×
1 1	0	+
½-1	0	+

It is evident, then, that the neutralisation point was reached when six parts of serum were mixed with one part of the venom solution (0 05 per cent)

TABLE V —*Experiments with Cobra Venom Serum and other Varieties of Snake Poison.*

The serum of the same rabbit as was used for the previous series of experiments was employed Two parts of this serum were mixed in Wright's sedimentation tubes with one part of each solution of each variety of snake venom as indicated below The snake poisons used were (1) cobra venom = C.V (2) *Daboia Russellii* venom = D V (3) venom of *Echis carinata* = E C.V , (4) venom of *Bungarus fasciatus* = B F V and (5) venom of *Hoplocephalus curtus* = H.C V The dilutions of venom were made with normal saline solution the measuring being accomplished by means of Wright's tubes. Observations were recorded from 8 to 20 hours after the preparations had been put up The following were the results obtained —

Serum = 2 Parts Venom Solution = 1 Part

Strength of venom solution per cent.	C V	D V	E.C V	B F V	H.C V
1·0	×	×	—	—	—
0·5	×	×	—	—	—
0·1	+	+	0	0	0

Bombay

"FOURTH DISEASE"

BY R. W MARSDEN M.D VICT M.R.C.P LOND &c.
HONORARY PHYSICIAN TO THE MANCHESTER CLINICAL HOSPITAL;
LATE MEDICAL SUPERINTENDENT TO THE MONSALL
FEVER HOSPITAL.

THE definite existence of a "fourth disease" distinct from measles, scarlet fever and rubella was first advocated by Dr Clement Dukes[1] in a paper on the Confusion of Two Different Diseases under the name Rubella (Rose rash) ' It is true that Thomas[2] after stating that according to his observations the exanthem of rubeola possesses a similarity to that of measles only and not the slightest to that of normal scarlet fever then wrote I am willing to admit the possibility of the existence of an equally important specific affection with a scarlatinous condition of the skin, although with all watchfulness I have as yet never met with such a form " Further Dukes[3] himself may be said to have foreshadowed the possible existence of two distinct diseases in the latter part of the paragraph which says 'Another remarkable fact about rose rash is that although both varieties of rose-rash may appear in the same epidemic, as I have shown, yet the measles variety like measles itself usually occurs in large numbers while the scarlet fever variety like scarlet fever itself always occurs to a much more limited extent. The definite statement, however was not made until this writer in the article first quoted[4] said

On the verge of the twentieth century we are only just discovering and not merely surmising that a fourth disease, perfectly distinct from measles, rose-rash and scarlet fever is to be distinguished."

However much we may regret the introduction of a source of greater confusion into our already indefinite ideas of the distinguishing features of the commoner exanthemata, yet as Ker[5] says we should all be working in the pursuit of truth and the easiest way to settle a question is not to burke it but to discuss it openly " For a consideration, therefore of this subject it is in the first place desirable to obtain a clear and detailed idea of the characteristics of the three diseases from which this is to be differentiated. The distinguishing features have however been already so thoroughly described and contrasted by Atkinson[6] Edwards[7] Dukes,[8] and others that it would be a work of supererogation to recapitulate all the points here. On account, however of the apparently great similarity of most of the features of fourth disease" with those of rubella and of the undoubted confusion which exists concerning this disease I think it is advisable that we should carefully consider some points which have a very important bearing on the differential diagnosis Despite the fact that Thomas[9] concluded that the exanthem of rubeola possesses a similarity to that of measles only it must be admitted that the majority of writers support the dual appearance of the eruption in this disease. Dukes himself[10] says In one epidemic of rose-rash the whole of the cases will resemble measles. In another epidemic of the same illness every case will resemble scarlet fever as occurred in an entire series of cases in the two schools where I was consulted comprising 16 cases at one school and 12 at the other In another epidemic some cases will simulate measles and others scarlet fever Watson Williams[11] says

There is undoubtedly a tendency for rubella to breed true so that in any given epidemic the cases mostly exhibit either the morbilliform or the scarlatiniform type but the occurrence of the two types together leaves no room for doubt that such two types of one and the same disease do exist " He describes an epidemic of rubella mild at first but later typically morbilliform, in which were two cases that would be termed fourth disease" by those who believed the scarlatiniform variety to be a distinct affection. One at least he says exhibited all the characteristic features associated with that case and others showed every gradation between the morbilliform variety of rubella and fourth disease It is unnecessary then to adduce further evidence in support of the existence of the two types of rubella.

[11] Brit Med Jour., Dec [illegible]

Now, in his original article advocating the recognition of a "fourth disease ' Dr Dukes says, when speaking of German measles (rubella) "I hope to prove to the satisfaction of the profession that this disease does not consist of two varieties of one kind, as I have hitherto contended with the profession in general, but that two definite and separate diseases have been confounded under one name," and Dr Ashby,[12] in the discussion on the early diagnosis of the acute specific fevers at the meeting of the British Medical Association in 1901, "believed with Dr Dukes that there were two diseases often included under the term "rubella," the common one with a long incubation period which mimicked measles and a rare one only diagnosable when it prevailed in epidemics and with a short incubation which mimicked scarlet fever" More recently Dr Dukes[13] states that the majority of cases of rubella begin and terminate with an eruption resembling measles, but that there is another set in which the eruption at the commencement is like measles and then finishes in patches like scarlet fever "It is not, however, such cases to which the name of 'fourth disease' is applied" One cannot help agreeing with Killick Millard[14] that it is to be regretted that the expressions used in introducing the subject should have been so indefinite as to allow such an erroneous conclusion to be drawn.

A differential diagnosis must then keep in mind the following types of disease (1) scarlet fever, (2) scarlatiniform variety of rubella, (3) morbilliform variety of rubella, and (4) measles According to Dr Dukes the rash of "fourth disease" presents a similarity to the eruption of scarlet fever only, so that types 3 and 4 do not need any further consideration. Turning, then, to type 2 one finds that this change in the appearance of the rash of rubella as it develops has been described by previous writers (Tonge-Smith,[15] J Brownlee, and Marshall[16]) I have already pointed out[17] that the eruption occurring at first as discrete spots may later in its coalescence retain throughout an exaggerated morbilliform appearance, but that this characteristic though not always persisting yet when it occurs is specially noted in certain regions (viz., the face, the limbs, and the buttocks), whereas on the trunk it tends to retain a punctate and scarlatiniform aspect. Moreover, when the exanthem is deep in colour the morbilliform appearance on the regions affected is still further enhanced, whilst with faint rashes, and usually in milder cases, it is distinctly more scarlatiniform. At the same time it must be remembered that the rash varies in intensity in different regions, so that it is essential to a correct appreciation to keep its polymorphic character constantly in mind.

Now, despite the description of the two types of rubella, it seems to me that there is a lack of definite information on the very point which enters most into the question So far as I have been able to gather writers are apparently unanimous that at the beginning of the attack the eruption is always morbilliform, consisting of discrete spots spread over the region affected It is evidently not sufficient to say generally that the rash was scarlatiniform. Dr Dukes admits that in its further development it may assume this character, one wants more especially to know what was the appearance at the onset. According to my own experience in the cases in which I have been able to note the appearance of the eruption, it has never had the close and even distribution of punctæ which alone would entitle one to use the term "scarlatiniform ' Were I to meet with such a series of cases I should, with Thomas,[18] require indisputable evidence to be brought forward of their arising by contagion from the usual rubeola exanthem resembling measles, and *vice versâ* to establish their identity. We may then, ask with Ker,[19] "What room can we find for the fourth disease?" He himself says that it may if it exists, occupy "one of two positions, either between measles and rubella or between the latter disease and scarlatina ' and further admits that he would be inclined to expect it in the former position Apparently Sir William Broadbent[20] would also favour this choice, for in reference to the subject he writes "I have said for many years that there were at least three kinds of measles ' On the other hand, from the reasons which I have given I am equally disposed to the demonstration of its position between scarlet fever and rubella, and since according to the description of "fourth disease" one gathers that from the first the eruption is practically indistinguishable from the rash of scarlet fever, one must, admitting the possibility of its occurrence, carefully examine the evidence adduced in its support. This testimony is supplied by Dukes in the citation of three epidemics in his original article. One finds on reading his account that the factors on which his conclusions are based may be grouped under the following headings (1) the inviolability of Cullen's law, (2) the fact that each disease possesses its own characteristic seed which is entirely *sui generis*, (3) inability to afford protection against the other exanthemata, (4) a suggested explanation of the real nature of the extensive mild epidemic of scarlet fever in 1892–93, and (5) clinical manifestations

1 According to Cullen's law, "one attack of an eruptive fever entails immunity from a second attack in the same individual during childhood." The rule is not absolute, but Dukes is of opinion that "the insignificant exceptions may be regarded as scientific curiosities only" On the other hand, the general opinion is against the view of such an extreme rarity of relapses and second attacks of the exanthemata, and this opinion seems to have the support of many of the practitioners who have had exceptional facilities for the study of these diseases—viz, Foord Caiger, Washbourn, Killick Millard, and Ker In this connexion Dukes would seem to infer that many of these are instances of patients with "fourth disease" contracting another infectious disease in the hospital Caiger,[21] however, who, one must admit, is in a better position to judge, points out (*a*) that he has not seen the "fourth disease" transmitted to the patients in the scarlet fever wards, (*b*) that in his experience cases answering to the description do not contract scarlet fever, (*c*) that the cases which do contract scarlet fever are those in which one felt originally that one would like to isolate, and (*d*) that relapses in scarlet fever are rare, occurring in about 1 per cent. of the cases in the Metropolitan Asylums Board (incidentally he mentions that there was no increase during the years 1892 and 1893), whereas if they were cases of "fourth disease" one would expect them to occur more frequently My own experience is exactly in accordance with the foregoing statements.

2 On this point I must confess myself at a loss concerning the exact meaning which Dr Dukes wishes to convey In so far as the micro-organism is concerned it is to be regretted that its specific nature will not assist us in this instance, since as yet its existence is a pure speculation, not only for the "fourth disease," but even for diseases with which it may be confounded Moreover, from what little we know of the micro organisms causing other infectious diseases, it is remarkable with what difficulty a clear line of demarcation can be made One has only to refer, as regards diphtheria, to the different forms of true diphtheria bacilli, their occurrence in healthy situations, the difficulty in separating them from so-called pseudo diphtheria bacilli, and as regards typhoid fever to the existence of Eberth's bacillus, bacilli of the Gaertner group, and of the coli communis type, in order to feel that from analogy the argument is by no means convincing But from our total ignorance on this point we must presume that Dr Dukes refers to the constant character of the manifestations by which we are enabled to detect its presence—i.e., to the symptoms diagnostic of the disease Here, again, we are familiar with what is spoken of as the protean aspect of disease, and we are accustomed to believe that its varied character in different individuals, dependent doubtless to some extent on the variability in the complex surroundings, or what we call the soil in each individual, is a rule which must always be kept in mind. Writing of rubella in reference to this point Thomas[22] says "Starting with the incontrovertible fact that anomalous eruptions of measles and scarlet fever occur the imperfectly characteristic nature of which is due solely to individual idiosyncrasies (which is proved by the fact they generate again, by contagion, cases which are perfectly normal) we must not expect of epidemic cases of roseola that their exanthem should be in all cases of a precisely similar type"

3 Dr Dukes informs us that the "fourth disease" gives no immunity to scarlet fever or rubella and similarly that these diseases afford no protection against it. The same fact

holds good for measles, but from lack of difficulty in the differential diagnosis there is no need for its further consideration. It seems to me that this statement is the crucial point in the whole argument and if proved would completely establish Dr Dukes's claims. Having completed an account of the three epidemics he considers that he has proved the definite existence of fourth disease" since he has shown (*a*) its occurrence concurrently with scarlet fever in the same epidemic, (*b*) that some patients had both diseases in the same epidemic (*c*) that one patient had scarlet fever followed by fourth disease" (*d*) that several had fourth disease" followed by scarlet fever, and (*e*) that although it has been confused with rose rash and regarded as a mere variety of rubella this conclusion is fallacious, since nearly one half the cases in an epidemic had already suffered from this latter disease within a year or two. The first four points are conclusions drawn from an epidemic which occurred some time previously and which the writer himself at that period regarded as one of the scarlatinal variety of epidemic roseo-rash. In these circumstances, I think one may legitimately question despite the high authority of the writer whether a sufficient degree of detail in events, connexions and appearances, which would be required to establish its identity even now after we have been made acquainted with its characters, would be accumulated and retained over such a period of time as to warrant the extremely important deductions which have been made

Concerning the first epidemic Washbourn[23] and Millard[24] consider that from the evidence adduced, beyond the statement that Dr Dukes now regards them as instances of 'fourth disease," there is nothing to compel one to differ from the original diagnosis of the scarlatinal variety of rubella. As Ker[25] says, the position would have been stronger if it had been noted what diseases the boys had had previously While this would not have been final it would have been interesting to know how many had had rubella before and, further whether Dr Dukes was himself satisfied as to the authority for the previous history

The second epidemic evidently consisted of two co-existent diseases which the two above-mentioned writers regard as scarlet fever and the scarlatinal variety of rubella, in agreement with Dr Dukes's original diagnosis. *I am of the same* opinion as Ker, that this would at any rate appear to be a reasonable view regarding it.

Concerning the third epidemic, from the facts observed in which the fifth point is deduced one finds that in it 19 boys were attacked 42 1 per cent. of them having previously suffered from rubella As pointed out in the leading article on the subject in THE LANCET of July 14th 1900 p. 114 this epidemic affords the strongest proof of the existence of a "fourth disease." On account of the high percentage of previous attacks of rubella it is impossible to imagine them as instances of this disease, since though relapses have been described, yet second attacks are practically unknown or at any rate undescribed. On the other hand, one is struck by the facts that in these cases the rash was quite indistinguishable from scarlet fever and that desquamation was often copious. Further, the almost continuous development of the cases during a period of 18 days strongly suggests a short incubation whereas Dr Dukes informs us that the fourth disease possesses a long incubation period practically identical with rubella. Finally one notes that scarlet fever had not occurred previously in a single instance. In such circumstances the difficulty of excluding the diagnosis of scarlet fever is very great, and one finds that it seems to have been dependent on the following facts (*a*) the occurrence of a very full rash without markedly accelerated pulse or marked rise in the temperature (*b*) the absence of peeling of the tongue about the fourth day (*c*) the absence in some cases apparently with an abundant rash of subsequent free desquamation and (*d*) the absence of sequelæ and spreading of the disease (with one exception) though the patients were removed from bed after five days and allowed to go out after eight days. I must confess myself in sympathy with previous writers who are of opinion that these points do not carry conviction that the disease was not scarlet fever On numerous individual occasions I have met with undoubted cases of scarlet fever exhibiting these peculiarities and it seems to me that the only unusual feature is the uniform persistence of the type throughout the 19 cases though as stated in the leading article which I have mentioned a "remarkable constancy of type is occasionally observed in connexion with a localised prevalence of scarlet fever"

4 In a previous article in THE LANCET Dr Dukes[26] hazarded the query whether the extensive but non fatal epidemic of scarlet fever which raged throughout the country in the autumn of 1892 and the spring of 1893 was not really to a large extent an epidemic of the scarlatinal variety of rubella, and more recently having considerably altered his opinion about previous epidemics of this disease, he naturally inquires whether it was not really to a large extent an epidemic of the fourth disease." It seems to me that in such circumstances the disease having been diagnosed as scarlet fever the most conclusive evidence ought to be obtained from the experience in the various fever hospitals during that period. In this respect, as I have already mentioned, Caiger informs us that the percentage occurrence of relapses after scarlet fever showed no alteration at that time, and he further adds ' Were I to come across even a short connected series of such attacks as would constitute a limited epidemic in a ward inhabited by patients convalescent from undoubted scarlet fever—and such outbreaks should be common enough surely if Dr Dukes is right as to its prevalence, infectivity and the frequency with which it is erroneously admitted into the scarlet fever wards—I would at once be prepared to register my allegiance to the fourth disease. Such an occurrence, however he has never yet succeeded in observing It seems incredible that such an extensive epidemic of another disease could have occurred and by admission to the various fever hospitals have been submitted to special scrutiny running the risks, too of giving and receiving infection without its identity being discovered. I cannot help feeling that the inclusion of such a suggestion is a distinct weakness on Dr Dukes's part. In this place also when laying stress upon the importance of the experience in large fever hospitals and knowing the relatively large number of doubtful and very mild cases which are certified for admission I must most strongly enter a protest against the statement made by Dr Dukes[27] that this experience 'is one-sided as slight cases of scarlet fever are not sent."

5. Turning now to the symptomatology as given in the tabular list we find that in this respect fourth disease and rubella appear to be very closely allied. In both diseases the premonitory symptoms, the seasonal prevalence the period of incubation, the subjective sensations, the condition of the throat, eyes, glands, urine tongue, pulse, and temperature, the course of the illness, and the absence of sequelæ are practically identical. The only distinctive points of difference apparently concern the rash the desquamation, and the period of infection. Concerning the exanthem, in contrast with the eruption seen in rubella, Dr Dukes says that in fourth disease' it will cover the whole body with a considerable diffuse rash in a few hours" Further its hue is bright rosy red and it is raised somewhat from the surface of the skin. As pointed out by Ker it is unfortunate that there is no mention of its occurrence on the face We feel bound to infer that it must be absent, though Weaver[28] specially draws attention to its appearance in this situation As regards desquamation in rubella it is absent or branny whereas in fourth disease" it may be slight or complete Its degree is stated to have no relation to the intensity of the eruption, though the slight rash is usually accompanied by little or no desquamation. On the other hand even when free it occurs mostly in small scales. Rubella seems to be most infectious in its earliest stages but according to Dr Dukes fourth disease" is not so very infectious at that period. Finally it is stated that rose rash like measles, occurs in large numbers usually whilst fourth disease" like scarlet fever is met with oftener in smaller epidemics.

It must be remembered that these slight differences are drawn from a consideration of three epidemics which as the late Dr J W Washbourn[29] has said are assumed to have been necessarily of the same nature though such an assumption from the evidence adduced is quite unjustifiable. It may be that the variety in the manifestations of fourth disease' itself is due to *differences in the three epidemics*. Thus it would be interesting to know the condition of the face as regards the exanthem in the first two epidemics which were originally diagnosed as rubella and in the third epidemic which, as already stated, could not possibly have been examples of this disease Similarly concerning the desquamation, one would like to have a detailed description with special reference to a separation of the different epidemics Necessarily such facts as its slight infectiousness in the early stages and its tendency to occur in limited numbers are less easy of corroboration or refutation, though if deduced from the more carefully observed third epidemic it may be remarked that they are quite in agreement with its suggested mild scarlatinal nature

Reviewing, then, the evidence upon which the differentiation of a "fourth disease" has been based, I think that it must be admitted that more conclusive details must be brought forward before we can feel satisfied that its definite nature has been distinguished. But I am far from denying its existence

LATE SENIOR AURAL SURGEON TO THE LONDON HOSPITAL SURGEON TO THE LONDON THROAT HOSPITAL.

With Supplementary Notes by W J PROCTER, M B , B S LOND

TOWARDS the end of November, 1896, a man, aged 40 years, attended at the ear department of the London Hospital with the following statement of his case furnished by Dr W J Procter, of Great Bookham, Surrey "The patient came to see me in September, 1896, complaining of fits He stated that his first fit occurred at Christmas, 1895, when he was brought home insensible, very cold, and with his face dusky He was seen by a neighbouring medical man but had recovered consciousness before his arrival He remained in a weak state for some time and could not bear a noise. The next attack happened during haymaking in 1896, he was again brought home insensible and remained so for 15 minutes, his face and general condition being the same as after the previous attack. From that time to September he was under treatment but had several fits It was about this time that I (Dr Procter) first saw the patient and was led from his remarks to suspect nasal disease This suspicion was confirmed on examination of the nose, there being marked hypertrophy of the middle turbinated bones, more especially on the right side. At the wish of his employer he was sent to a general hospital, being made an in patient on the medical side. Here the nasal condition was dissociated from the symptoms and the fits, regarded as epileptiform in character, were referred to an attack of sunstroke from which he had suffered 15 years previously He remained an in patient for a fortnight, during which time he had two seizures, and was then treated as an out-patient for seven weeks The attacks occurred now almost daily, his memory became defective, and he wept frequently On one day he had three attacks in which his wife states he lay like one asleep, except that his throat got full and his eyelids twitched. On recovery he was extremely prostrate and excitable, the least contradiction bringing on an attack. There was some evidence of an antecedent aura, as he knew when a fit was coming on, but could not describe the feeling"

When I (Dr Woakes) examined the patient at the hospital on the first-named date he was in feeble health and his spirits were very depressed. Nasal examination showed enlargement of both middle turbinated bones, the left to a slight extent only, while the right presented a firm, nodulated tumour, occupying the anterior ethmoid region of the nostril from its outer wall to the septum So firmly did it press against the latter that it was impossible to pass the loop of a snare between the opposed surfaces It was therefore removed with my cutting ring forceps The sections showed expansion of the intertrabecular spaces but no considerable cyst or cavity He attended several weeks as an out-patient when feeling quite well and having had no return of the attacks he discontinued his visits. In the early part of the year 1901 some four and a half years after the operation, Dr Procter reported on his condition that he "had not had a single attack since the operation and described himself as 'not like the same man'"

Up to this time it does not appear that Dr Procter had ever actually witnessed one of these attacks, but there seems to have been no doubt in the minds of those physicians who did observe them that they were of an epileptic character—a quite justifiable view of the case considering the absence of any other generally recognised alternative class of disease to which it might otherwise have been referred. Three symptoms, however, mentioned by Dr Procter as associated with the fits seemed in my mind to differentiate this case from one of true epilepsy and to transfer it to the group of vertigos due to disturbance of the equilibrating apparatus of nasal origin, an opinion which the sequel tends strongly to confirm. The three symptoms above referred to are (1) hyperacousis, indicated by the distress occasioned to the patient by the occurrence of loud noises and evidencing implication of the cochlear portion of the octavus nerve, (2) the tendency to uncontrollable weeping, and (3) loss of memory These symptoms, but especially the last two, are shown by experience to be in constant association with chronic forms of vertigo of nasal origin They point to extension of the reflexes to the vestibular branch of the octavus supplying the end organs of equilibration That these symptoms were the outcome of reflex irritation and were not due to central lesion is evidenced by their immediate and complete cessation following removal of the exciting cause

After an interval of over four years, during which time the patient had no recurrence of the symptoms above detailed, I was informed by Dr Procter in July, 1901, that the man had recently experienced "one very bad seizure and several slight ones" A few weeks afterwards he had the opportunity of witnessing an attack and was good enough to send me the following description of it The patient "lay as if he were asleep with no convulsive movements of the limbs During this time there occurred several violent contractions of the lower jaw The jaw moved up and down so quickly and violently that the room on the floor of which he was lying quite shook. There was also violent pulsation of the carotids The skin was warm and there was no marked rigidity of the body" Particulars of other attacks occurring at this time and showing variations of the symptoms in different seizures state that "he always knew when an attack was coming on and generally managed to sit or to lie down. There was a sort of premonitory aura which the patient described as a cold chill starting in the feet and passing up the body to the head, when he experienced a darting pain and became unconscious. The period of unconsciousness varied from 15 minutes to two or three hours The face was pale Sometimes the eyes were open and the eyeballs rolled (nystagmus), but more frequently the eyes were shut. The breathing was always quiet. There was no struggling and no twitching of the face or limbs. These in some of the attacks became very stiff, so that he could be lifted without the joints bending If the attack was of considerable duration the skin became very cold There was no loss of control over the sphincters and he never bit his tongue Recovery was gradual, the mind being quite vacant at first, and he was quite oblivious to what had happened during the attacks Catalepsy and malingering were suggested to the minds of the medical men who attended him, but both were rejected as inapplicable to the case"

I saw the patient again in the autumn of 1901. The ethmoid region of the nose had considerably changed as regards the left middle turbinal. In the interval of four years the disease in it had developed to such an extent that it presented much the same enlargement as that of the right side in 1896 It differed, however, from it inasmuch as the enlarged osseous structures were covered with abundant soft proliferations, especially were these abundant on the inner surface adjacent to the septum The stump of the right turbinal had not materially changed since the operation in 1896 It was therefore inferred that the recrudescence of the symptoms was due to the subsequent morbid development of the left turbinal. On Nov 13th, 1901, the patient was admitted to the London Throat Hospital under the care of Mr Claud Woakes who ablated the entire left middle turbinal bone as well as the stump on the right side under anæsthetics On the third day the patient was up and about the ward, no symptoms whatever following the operation. He left the hospital and returned to his home on Dec. 6th, 1901. In reply to recent inquiries Dr Procter quotes from the steward of the estate on which the patient is employed: "He has not had any more fits since his last operation. He seems to be quite well, much better than I have ever seen him before."

This case may be regarded as an extreme type of a class of which there are many examples—that is to say, of vertigo of nasal origin, with its varied and often curiously puzzling phenomena. Though constituting a group of disease which is *sui generis* and quite distinct from epilepsy it sometimes simulates one or other of the forms embraced by this latter term. It has, however, these advantages over true epilepsy: the existence of a recognisable *causâ causans*—viz., ethmoidal disease and its almost certain cessation when this disease is radically dealt with.

It would be advantageous to determine the exact area within the nostrils irritation of which will induce epileptiform symptoms. It must be granted that the evidence bearing on this point is not quite conclusive. In Dr. Procter's patient this area was recognised as the portion of the septum nasi, including the septal nerve traversing it, against which the mass of diseased spongy bone impinged. But I have on record other cases in which irritation of the same portion of the septum was associated with quite other symptoms. Thus one patient who had for weeks been the subject of incessant hacking cough as soon as a mass of granulation tissue was pressed away from the septum experienced immediate cessation of the cough, which cessation remained permanent on destruction of the growth by the cautery. Another example occurred in a sufferer from chronic asthma, in whom a grave attack of suffocative dyspnœa was relieved even during the process of cauterising a soft mass which touched the septum in the situation indicated. Respecting these latter examples it is to be observed that the symptoms were excited by soft growths which tickled rather than pressed upon the septal mucous membrane. In the numerous instances of vertigo occurring concurrently with the presence of ethmoid disease the middle spongy bone has usually assumed the character of a hard mass more or less resembling that above described as existing in the present case.

Of growths presenting the characteristic of great hardness by far the most remarkable in my experience occurred in a man, aged 38 years, who was sent to me for the treatment of nasal polypus. Underlying a covering of polypi in the left nostril was a firm mass corresponding in situation with the left middle turbinal bone and tightly wedged between the septum and the outer wall of the nose. It was removed entire by means of the curved gouge and weighed a few hours thereafter 93 grains. The whole mass was solid, the inferior half being of ivory density and hardness, the remainder being finely spongy.[1] (It is necessary to remind the reader that the pathological condition just described is quite an exceptional one. For though exostosis in minor degrees is not by any means rare in the inferior turbinals this is the only instance of its presence in the middle spongy process that has occurred to me in 25 years' experience of nasal surgery. The history of this patient, moreover, suggests that the disease was congenital, or at any rate that it commenced soon after birth—the polypi being a much later development.) The reflexes excited by the presence of this mass differed from any of those exhibited in the foregoing cases. From earliest childhood this patient had been subject to severe attacks of gastric disturbance which had recurred with but little variation up to the time of the operation. The attacks commenced with shivering followed by vomiting and sweating and left him in a state of great prostration; he was never free from uneasiness in the region of the stomach and suffered much from frontal and basal headache. He experienced one or more such attacks every week and they lasted from two to three days. It is not surprising that in consequence of this life-long affliction his education had been so far neglected that he could neither read nor write, though able to participate in the practical side of a large business. After removal of the mass in question these symptoms ceased entirely and with the exception of one slight recurrence during convalescence from the operation he has since been quite free from them. This patient reports himself every year or two and when last seen was the picture of robust health.

So far the cases thus briefly cited afford no decisive clue to the exact area of the Schneiderian membrane irritation of which is responsible for the symptoms. Neither do they afford definite information respecting the physical nature of the growth as determining the character these will assume. The one point they do establish is the potentiality of certain forms of nasal disease to induce a variety of symptoms, usually of grave aspect and of long continuance. That these sometimes approach closely enough to the epileptiform state to be easily confused with it is apparent from the case first above reported. Possibly its record will be found to contain some details which may aid in the differential diagnosis of such occurrences in the future.

Harley-street, W.

A CASE OF

ACUTE MENTAL DISORDER, PROBABLY TOXIC IN ORIGIN, SECONDARY TO INFLUENZA

RESULT OF THE NECROPSY PRACTICALLY NEGATIVE, EXCEPT THAT THE BACILLUS DIPHTHERIÆ WAS FOUND IN THE BLOOD

BY ALICE N. V. JOHNSON, M.D. BRUX., L.R.C.P. & S. EDIN., D.P.H. CANTAB.

AND

EDWIN GOODALL, M.D., B.S., M.R.C.P. LOND.
JOINT COUNTIES ASYLUM, CARMARTHEN

A MARRIED woman, aged 43 years, was admitted into the Joint Counties Asylum, Carmarthen, on May 21st, 1902, suffering from an acute confusional condition. It was her first attack and had lasted for from three to four months. At Christmas, 1901, she had a severe attack of influenza (this was believed to be correct by the medical man who subsequently attended her) after which she became gloomy and depressed, eating and sleeping little. In March, 1902, she became very restless, excitable, and destructive, tearing her clothes and rushing about the house attacking people if they interfered with her. These symptoms increased until she was admitted. One sister suffered from fits. Otherwise there was no family history of mental or nervous disease. The patient was described as of temperate habits and this was borne out by the necropsy.

On admission the patient was very restless, resistive, hostile, destructive, and dirty in her habits. She was very noisy and shouted incoherently day and night. She was very exalted in her ideas, made mistakes in identity, had hallucinations of vision, and freely expressed delusions of persecution. She was quite unconscious as to time and place and could not answer any questions. She was a strong, well-nourished woman. Her trunk and limbs were covered with bruises; her face, hands, and feet were cyanosed. She had some old aortic regurgitation and the heart was enlarged. Both eyes were covered with old interstitial keratitis. She had marked tremors of the lips, tongue, and hands. She refused to walk. Subsequent examination pointed to an inability to walk owing to weakness of the legs. Her pupils were equal in size, regular in contour, moderately dilated, and sluggish in reaction to light and to accommodation. The lungs were normal. The teeth were very bad and the gums were inflamed. The tongue was clean and the bowels were well open. The patient struggled too much to allow a view of the throat. There was no indication for using the gag for this purpose. A diagnosis of acute confusional state, possibly a phase of dementia paralytica, was made, the causation being probably influenza. Prognosis: "Probably fatal."

On May 22nd the report was that she had passed a very restless night and was very noisy although she had been given hypodermically five minims of a ½ per cent. solution of liquor hyoscyami. She took all her food. She continued in this muttering unintelligible condition with restlessness but taking her food well until the 27th. A large abrasion appeared over her sacrum the result of banging herself on the bedstead. The tongue became very dirty, the gums were covered in sordes, and the breath was very foul. Sleep was very broken. On the 28th moist sounds were heard over both lungs, the pulse was very quick and irregular, there was no increase in temperature. She was placed on fluid diet, which she took well, and on carbonate of ammonia and strychnine every four hours She died at 9 50 A.M on the 29th.

---

[1] Examined and reported on by Dr. E. B. Waggett in June, 1894.

Necropsy —A post-mortem examination was made at noon on May 30th The body was well nourished, there were no superficial lesions The calvarium was of normal thickness and fairly dense, no exostosis was present. The dura mater was adherent anteriorly The convolutions were normal with regard to size and arrangements The pia mater peeled easily, some slight opacities were present over the sulci, otherwise the leptomeninges were normal, there being only slight increase in vascularity The basal arteries and ventricles of the brain were normal. The mid brain and cerebellum were normal. Vascularity of the grey and the white matter of the brain was only slightly increased. There were no focal lesions The left ventricle of the heart was hypertrophied and the myocardium was friable, slight atheroma of the aorta was present and the aortic cusps were thickened. There was some slight congestion of both lungs The pharynx and the larynx and trachea were very congested Some old mechanical congestion of the liver was present and the gall-bladder was distended The spleen and alimentary canal were normal. In both kidneys the capsule was adherent, but they were normal in other respects. The peritoneum was normal As regards the uterus there was a polypus at the internal os and some old endometritis was present, the ovaries and tubes were normal.

Some small pieces of brain were immediately frozen and sections were stained with aniline blue black and examined They showed some slightly increased vascularity but nothing else was noted A tube of blood serum was inoculated with strict antiseptic precautions with some blood from the right side of the heart, and another with cerebro spinal fluid from the lateral ventricle. Both tubes were incubated at 35° C On June 1st and 2nd no growth was present on either tube. On the 3rd there was a slight fine growth on the tube inoculated with the heart's blood. A film was made and a fairly long bacillus with clubbed ends was demonstrated, staining with simple stain and with Gram's method No growth was present on the tube inoculated with cerebro-spinal fluid On the 4th both tubes were sent up to Dr D N Nabarro of University College, London, who kindly made a subculture and examined films, and reported that the growth was a pure growth of the bacillus diphtheriæ and that the tube inoculated with the cerebro spinal fluid showed no growth at all The medical man who certified the patient was asked if there were any diphtheria near her home. He replied "There has been none in the immediate neighbourhood as far as I know, but plenty of it at distances varying from two to five miles away"

Remarks —Clinically the condition is best described as acute confusional insanity The necropsy negatived dementia paralytica and acute delirious *mania*. The patient appears to have been the subject of toxæmia, though the precise nature of the toxic agent is obscure. The record of the mental disorder dates from the supposed attack of influenza, although it is rather remarkable that there should have been marked exacerbation of mental symptoms, without any recrudescence of the disease, from two to three months after their appearance Again, the patient's physical condition was good (she was a well-developed, powerfully built woman), not that which one would expect to find in an individual suffering from influenza or its after effects The negative result of the necropsy, beyond the slightly increased vascularity of the brain substance and the cardiac changes, was very remarkable. There was nothing in the respiratory tract to raise the suspicion of diphtheria, although certain parts were much congested

As there had been no question of diphtheria during life no swab preparation was made. Indeed, there was no thought of diphtheria at the necropsy and tubes were inoculated from the blood and cerebro-spinal fluid on the possibility of finding some organism which might be held accountable for the toxæmic symptoms manifested. It is a remarkable fact that such acute mental disorder should have existed with such trifling macroscopic evidence of disease in the brain and its membranes Microscopically Nissl's method was unfortunately not used, but the aniline blue-black method showed only slightly increased vascularity

As regards the presence of the bacillus diphtheriæ in the blood observers have pointed out that this is sometimes found in the organs (lung, liver, &c.) post mortem, and it is conjectured that the bacillus has, in such cases, passed into the blood stream after death. This occurrence, however, is, as far as is known, very rare. The patient may have had diphtheria, and this disease may have been the cause of her later mental symptoms In addition to the organism in the blood there were the facts of the congestion of the upper air passages, the apparent inability to stand, and the prevalence of diphtheria in the neighbourhood of her home

Appendix —Some sections from the parietal region, that had been hardened in Müller's fluid and stained with Kulschitzky's hæmatoxylin solution, were examined microscopically The tangential fibres and the superradiary were found to be scanty and degenerate

NEW HOSPITAL FOR WOMEN

A CASE OF PLEURO-PNEUMONIA SIMULATING ABDOMINAL DISEASE.

(Under the care of Dr JANE H WALKER.)

WE have drawn attention elsewhere (p 446) to the risk which exists of mistaking intrathoracic disease for a serious affection of some abdominal viscus, and in this connexion the following case is of great interest, for the history of the patient and the course of the disease pointed very clearly to gastric ulcer, yet the morbid condition present was a pneumonia with a localised pleurisy

A board school teacher, aged 25 years, was admitted into the New Hospital for Women on May 24th, 1902, complaining of anæmia She was in her usual health till September, 1901, when she began to grow breathless and pallid and to have swelling of the legs and abdomen, puffiness under the eyes, noises in the head, and giddiness She had a cough and brought up some expectoration which was occasionally blood streaked In February, 1902, she had influenza and went to Worthing for five weeks to recruit her health but came back no better She did her work as a teacher till her admission into the hospital, but she was evidently considerably ill, being constantly sick and suffering from most obstinate constipation. On inquiring further into her past history it was ascertained that she had an attack characterised by all the symptoms of gastric ulcer six years before when she was in Charing Cross Hospital and again a second seizure of the same nature three years since. She had pleurisy as a child but no other illnesses bearing on the case.

On admission it was noted that she was very anæmic and was very well nourished, her weight having increased by 14 pounds during the past year—i e., during the time of her increasing illness She had hæmic bruits over the cardiac area. No abnormal signs in the lungs were detected. The temperature was 102 4° F, the pulse was 112, and the respirations were 28 The abdomen was somewhat distended but it moved fairly well. There was slight tenderness on pressure on the right side, most marked in the right iliac fossa, where there was some increased sense of resistance The note was resonant all over and there was no dulness in the flanks. The blood count showed very considerable diminution of hæmoglobin and some decrease of blood cells and no leucocytosis.

From admission on May 24th to the 31st it was noted that the patient's temperature went up to points varying from 103° to 105° Suddenly and unexpectedly at the same time the pulse rate varied from 90 to 128 and the respirations from 18 to 54, neither pulse nor respiration having any direct relation to the temperature. Her chest, which was carefully examined every day, showed no abnormal signs. On June 1st, on the advice of Dr Walker's surgical colleagues who regarded the case as probably one of abscess in the abdomen either in connexion with the appendix or tracking down from a perforated ulcer of the stomach, it was decided to make an exploratory incision. Accordingly, on

June 1st, under ether as the anæsthetic, this was done and the abdominal and pelvic viscera were carefully examined. Beyond a very small quantity of clear serous fluid in the abdominal cavity nothing abnormal was found The right lung was percussed while the patient was anæsthetised and no dulness was found. A large exploratory needle was passed into the right pleura and a small quantity of blood was drawn off. This was subsequently examined bacteriologically and no organisms were present On the following day impaired breath sounds were noticed at the right base and on the next day friction was heard. During the following week the patient had several attacks of breathlessness and also on several occasions the temperature reached a high level—105 8° being once noted. The signs in the chest gradually developed, giving those of a limited pleuropneumonia, some muco-purulent material being expectorated which was examined for both tubercle bacilli and other organisms with a negative result. The signs in the lung gradually cleared up and when the patient left the hospital on July 16th slight impairment of the note at the right base and prolonged expiration at the right apex were all that remained.

Remarks by Dr WALKER.—The above case belongs to the class described by Mr H. L. Barnard in his interesting paper published in THE LANCET of August 2nd p 280 It is worth recording both from its intrinsic interest as well as from the fact that it is another case of a kind where a mistaken diagnosis is not impossible, the consequences of which might be most deplorable. The case is obviously one where a correct diagnosis was extremely difficult The symptoms and previous history of abdominal trouble, the vomiting pain tenderness and localised resistance all pointed to abdominal disease. The chest signs were negative and so clearly was the possibility of chest mischief before the mind that the lungs were daily examined, but nothing abnormal was detected nor were the respirations unduly quickened.

LIVERPOOL ROYAL INFIRMARY

TWO CASES OF "RELAPSING" GASTRIC ULCER.

(Under the care of Dr J HILL ABRAM and Mr W THELWALL THOMAS.)

THE value of surgery in intractable ulcers of the stomach and duodenum is very clearly shown by the following two cases The tendency to cicatrisation in gastric ulcers varies in different cases, but that some heal spontaneously there can be no doubt. According to Einhorn[1] 50 per cent. of all cases of gastric ulcers heal completely without any severe complication but a large proportion require active surgical treatment.

CASE 1.—A spinster aged 42 years was sent to Dr Abram by Mr R. A. Jones of Holywell on Dec. 8th, 1900. She had always been delicate. In 1896 she had a bad attack of gastric trouble which lasted for 18 months and recurred at short intervals until October 1900 when severe pain in the stomach and back supervened and was accompanied by vomiting The vomited material was copious (two pints) On admission to the Liverpool Royal Infirmary she was emaciated slept badly and complained of headache dizziness and pain in the stomach. The molar teeth were greatly decayed in both upper and lower jaws The *tongue was dry and there was a constant bitter taste in the* mouth Ingestion of food caused dull aching pain in the stomach which persisted until vomiting occurred The vomited material was copious, smelling strongly of butyric acid. The bowels were very costive. Physical examination of the abdomen revealed marked tenderness in the epigastrium a dilated stomach extending well below the umbilicus and an *irregular* flattish mass in the upper right quadrant of the abdomen. The urine was scanty and alkaline (fixed alkali) With routine treatment the patient improved to such an extent that from Dec. 14th to Jan. 3rd there was no vomiting and in fact, the patient considered herself well. However Dr Abram considered that an operation was advisable and the patient was transferred to the care of Mr Thelwall Thomas in January 1901 On opening the abdomen a mass of adhesions was found in the pyloric region which were covering a duodenal ulcer lying just beyond the pyloric ring and so situated anatomically that excision was impracticable. The surface of the ulcer was scraped and pyloroplasty was performed. She made an uninterrupted recovery and had remained free from any gastric symptoms up to the time she was last seen (July 1902) and there is now no trace of dilatation of the stomach.

CASE 2.—The patient was a nurse aged 26 years. The first gastric symptom, vomiting occurred in February 1899 and was definitely associated with mental shock. Food caused discomfort but not actual pain. After a month's rest no symptoms appeared for seven months. From this time (October 1899) constipation was marked and slight pain after food was frequent. In March 1900 Dr Abram saw her for a severe attack of pain in the epigastrium with a slight degree of collapse Mr Thelwall Thomas saw the case with him and it was decided that perforation in the general cavity of the peritoneum had not occurred and that immediate operation was not indicated. On May 8th she left the infirmary practically free from all symptoms and during a three months holiday could golf and cycle. *After returning* to duty she had occasional attacks of colicky pain. In November 1901 she had a septic throat and as the temperature fell, a severe attack of abdominal pain came on. Dr Abram was now able to detect a lump in the epigastrium lying to the left of the middle line. Although by careful dieting and attention to the bowels this patient could be kept free from pain, yet she was always in danger of a relapse, and moreover was off duty nine months in three years—a serious matter to a nurse. Dr Caton also saw the patient and agreed as to operation. Mr Thelwall Thomas operated in December 1901. There was a dense mass of adhesions, covering an ulcer of the stomach. The ulcer lay on the lesser curvature rather nearer the cardiac than the pyloric end of the stomach. The ulcer and adhesions were excised The patient made a good recovery from the operation and *has remained well up to the time of writing* (August 1902).

Remarks by Dr ABRAM.—I wish to record these two cases because I believe physicians will have to consider the question of surgical interference in cases of chronic gastric ulcer *or as* they might well be called "relapsing" gastric ulcer I should like to emphasise the fact that in both these cases relief was obtained by ordinary treatment, and yet in Case 1 life was becoming a burden and in Case 2 the repeated relapses were seriously interfering with the patient's training as a nurse In Case 2 the adhesions were extremely dense and in fact, Mr Thomas thought that he had a tumour to deal with Subsequent microscopical examination by Dr E. E. Glynn showed however simply scar tissue Although not tumour the adhesions were so tough that their removal was most difficult and it would have been in my opinion absolutely hopeless to *interfere successfully for an acute* perforation It seems to me, therefore that surgical intervention should be invoked during a quiescent period Finally the term which I have suggested for these cases—viz "relapsing"—needs a word or two of comment. The cicatrisation of a true gastric ulcer is a much rarer thing in my opinion than is commonly believed I have no note of such a condition post mortem, and the pathologist to the infirmary Dr Glynn has only found one in a hundred cases in which the stomachs were specially treated and any cicatrix could have been readily detected. Many writers on gastric ulcer hold that the cicatrices are overlooked hence Dr Glynn's experience is important. From the history of the above two cases it is obvious that the symptoms may all disappear and yet the ulcer has not cicatrised, it has merely become callous The cause of *relapse is obscure*; errors of diet and so on, account for some cases but Case 2 is of interest for in this instance a severe relapse attended, or rather followed, a septic throat and it may well be that infection has much to do with relapses This again, emphasises the necessity for most rigorous attention to the state of the mouth in all cases of gastric ulcer

---

VACCINATION GRANT.—Mr J Chestnutt B.A., public vaccinator for Howden, East Yorkshire has for the second time been awarded the special grant for the efficient state of vaccination in his district.

[1] Quoted by Robson and Moynihan, Diseases of the Stomach and their Surgical Treatment p 100.

Reviews and Notices of Books.

Dangerous Trades the Historical, Social, and Legal Aspects of Industrial Occupations as Affecting Health By a number of Experts Edited by THOMAS OLIVER, M A Durh , M D Glasg , F R C P Lond , Medical Expert on the White Lead, Dangerous Trades, Pottery, and Lucifer Match Committees of the Home Office , Professor of Physiology, University of Durham , Physician to the Royal Infirmary, Newcastle upon Tyne London John Murray 1902. Pp 891. Price 25s net

IT is now 20 years since the late Dr Arlidge published his book on "Hygiene and the Diseases of Occupation" The work done by Dr Arlidge has not been hitherto, and is not yet, sufficiently appreciated, but the seed which he sowed is bearing fruit and the future historian of dangerous trades will not fail to give due credit to a man who worked alone and unrewarded The writings of Dr Arlidge, it is true, lacked the literary skill which has made those of Sir John Simon so popular, but his book will outlive many more pretentious works A very large amount of information concerning dangerous trades has been accumulated during the last few years, and most of it has been published in the annual reports of the Chief Inspector of Factories and Workshops which are issued by the Home Office A book containing all the latest available information on dangerous trades and the diseases induced by them has long been wanted The work edited by Dr Oliver has been designed to meet this want "This," Dr Oliver tells us in the opening passage of his preface, "is the first occasion on which, on the special lines indicated in this book, any adequate attempt has been made in this or any other country to deal with the conduct of trades and other occupations in respect to the dangers to life and health to which the workers are liable" The field covered by "dangerous trades and occupations" is, as the editor goes on to say, a very wide one, and he used a wise discretion when, feeling that there is "no one person competent to deal adequately with the whole," he decided to engage the coöperation of a number of writers to contribute articles on the various subjects with which the volume deals The book is written not only for medical men but for the educated public, and it is hoped also that it will be of assistance to members of both Houses of Parliament From what has been said it will be seen that the task which Dr Oliver set himself was by no means light and was beset with difficulties from the beginning Two of these are at once apparent. In the first place, which are the industrial occupations? Dr Oliver includes the army and "the marine services" A second difficulty was, how is it possible to write on diseases in such a way as to be instructive to the general public and at the same time to be of use to medical men? The task appears to be almost an impossible one

The introductory chapter is written by Dr Oliver It appeals rather to the "educated public" and to Members of Parliament than to medical men The next two chapters comprise an historical sketch of the Development of Legislation for Injurious and Dangerous Industries in England, and the Regulation of Injurious or Dangerous Occupations in Factories and Workshops in some of the Chief European Countries The history of factory legislation is poor in facts and is not up-to-date, having been written before the passing of the Factory Act of last year

Dr John Tatham of the Registrar General s office contributes a chapter on the Mortality of Occupations and one on Dust producing Occupations These are both admirable. The facts given may be relied upon as being accurate. The statements are made clearly and concisely No extraneous matter is introduced The chapter on the Safeguarding of Machinery is written by Mr H S Richmond, H M Superintending Inspector of Factories The subject is treated by one who is thoroughly familiar with the subject on which he writes and who can clearly express what he has to say Mr Richmond has embodied the provisions of the Factory Act (1891) in so far as they bear on the subject on which he treats and his work is done in that thorough and scholarly way which is possible only to one who has an accurate knowledge of his subject and the power of literary expression

A chapter on Lead and its Compounds is written by Dr Oliver who has of late been much engaged in the subject on behalf of the Home Office His work is familiar to readers of THE LANCET and it need only be said that this chapter is not unworthy of his reputation. Dr Oliver contributes also articles on China and Earthenware Manufacture , Phosphorus and Lucifer Matches , Indiarubber, and the dangers incidental to the use of Bisulphide of Carbon and Naphtha , Dry Cleaning by means of Benzine , on the Use of Inflammable or Spirit Paints , on Flour Mills , on Diseases due to Working in Compressed and Stagnant Air , on Diseases due to Diminished Atmospheric Pressure , on the Effects of Concussion of the Air , on the Iron and Steel Industries , on Diseases due to Excessively Repeated Muscular Actions , and on Miscellaneous Trades, amongst the workers in which are included tobacco manufacturers and cooks, coal-heavers and housemaids, workers in sequoia wood and chimney sweeps Finally, the editor has written on "Dust Women" and Dust as a Cause of Occupation Disease. Like dust itself, the information contained in this book on the subject of dust is very irregularly distributed Of Dr Tatham's article on dust-producing occupations mention has already been made The dust women of whom Dr Oliver writes are, of course, those unfortunate people who sort rubbish for the metropolitan boroughs and for contractors The chapter on dust as a cause of occupation disease is illustrated by a number of micro photographs, most of which are of little practical use Ganister crushing (of which a good account was given in the Factory Reports for 1900), mill stone building, and steel grinding are dusty occupations which are separately described Dr Morison Legge contributes an instructive chapter on the Dangers in the Use of Mercury and its Salts and one on the Lesions resulting from the Manufacture and Uses of Potassium and Sodium Bichromate.

As editor of the book Dr Oliver must be held responsible for the selection of the writers, for the allocation of the subject on which each contributor was to write, and for the general arrangement of the book It is not easy to account for the selection of some of the contributors There is an unnecessary overlapping in some of the articles and the general arrangement of the contents of the book cannot be explained except on the supposition that it is the result of chance. In the next edition of this book, which is certain to be wanted and of which the publication should not be delayed (for the present volume is already in parts out of date), the editor will do well to arrange the contents on some definite principle The book, however, possesses a full table of contents and a moderately good index, so that any reader can usually refer to any point on which he requires information

We welcome the present volume as the standard book on dangerous trades The parts to which we have called attention are amongst the best in the book and it would not be right to disguise the fact that there are some chapters in the present edition which should be eliminated, some which should be entirely rewritten, and very many which require editorial supervision

A Practical Manual of Insanity By DANIEL R. BROWER, M.D, Professor of Nervous and Mental Diseases in Rush Medical College, and HENRY M BANNISTER, M.D formerly Senior Assistant Physician to the Illinois Eastern Hospital for the Insane. Philadelphia and London W B. Saunders and Co 1902. Pp. 426. Price 13*s.* net

THE past three or four years have been marked by the making of many text-books in insanity a thing due partly at least to the fact that a knowledge of mental disease is become increasingly important, if not compulsory in the higher medical examinations The aim of the present work is to present to the student and to the general practitioner the essential aspects of mental disease, and to give an 'intelligible and up-to-date statement of facts " With these objects after a preliminary sketch of the causes of insanity a few pages are devoted to the commoner symptoms of mental diseases such as alteration of spirits hallucinations and delusions and aberrations of the will Then follow brief accounts of the examination and general treatment of patients. The preceding portion occupies 130 pages The next chapter deals with the Classification of Mental Disease and while it summarises several schemes of classification propounded by many authorities the subject is not handled with particular discrimination. The next 250 pages are devoted to systematic descriptions of the various types of insanity under the following headings Primary and Secondary Confusional Insanity Melancholia, the Toxic Insanities due to Alcohol Morphia, Cocaine, and other Drugs General Paralysis of the Insane Organic Dementia Epileptic, Hysterical and Hypochondriacal Insanity, Adolescent and Senile Insanity, Recurrent Degenerative Mania, Circular Insanity, Paranoia, Moral Insanity Imbecility and Borderland States between Sanity and Insanity The descriptions given of the various insanities are concise and clear but by no means sufficient for diagnostic purposes, and the frequent absence of clinical cases or details of clinical and pathological interest detracts somewhat from the practical value of the book. This will doubtless be remedied in future editions but in its present form the book can have but a limited scope of usefulness to students or practitioners.

Geburtshilfliche Operationslehre für Studierende und Aerzte. (Text book of Obstetrical Operations for Students and Practitioners) By Dr FELIX SKUTSCH A.O Professor an der Universität Jena. With 145 illustrations in the text. Jena Gustav Fischer 1901. 8vo pp. 348 Price 8 marks.

THIS book is not intended to be a text book of midwifery It is concerned with the indications for and the best methods of carrying out, the various obstetrical operations Primarily a manual for students it should prove of service to the general practitioner After an introductory chapter upon the Prevention of Puerperal Fever the application of forceps in all the presentations suitable for the use of that instrument is discussed Professor Skutsch does not appear to have a very well defined view of English practice at the present day since he says in describing the use of forceps, that while in France and Germany the forceps are often applied to the head while lying high up in the pelvis in England they are mainly used when the head is low down in the pelvic cavity—a statement which certainly does not represent the usual practice in this country He does not appear to approve of *axis-traction* forceps and the section devoted to these is somewhat scanty and poor No mention at all is made of the modern and improved forms and the many advantages of the instrument do not appear to be appreciated by the author There are, of course, many practical points in which the advice *differs from* that usually given by English obstetricians and this adds to the interest of the book For instance, the author recommends that when the forceps are applied to the head while situated low down in the pelvis they should be passed by the right hand applied to the shanks, one or two fingers being placed between the two blades. In this way he thinks there will be less likelihood of injuriously compressing the child's head. In the application of high forceps while the left hand is used to make traction on the axis of the handles of the forceps, the right is used to make pressure downwards at right angles to the long axis of the instrument, the patient lying in the dorsal position By this method, known as Osiander's axis traction is carried out. In many instances the practice of producing rotation of the head by the forceps is recommended a plan not much in vogue in this country In cases of premature rupture of the membranes and incomplete dilatation of the cervical canal the *introduction* of a hydrostatic dilator into the vagina is suggested. This is to prevent the escape of the liquor amnii, to promote dilatation of the cervix, and to set up uterine contraction. We imagine that most English obstetricians would place the bag in the cervical canal and not in the vagina. To render the rotation of the body more certain in dorso-posterior transverse presentation Professor Skutsch brings down both legs. By this method he thinks the rotation of the back of the child to the front is more certainly obtained and the arms are less liable to become extended In transverse positions of the child with presentation of the back Deutsch's method of rotating the whole body of the child upon a transverse axis is described and figured No mention is made of the vertical elongation of the head which occurs in cephalotripsy The author does not consider that symphysiotomy is an operation suitable for private practice, and throughout the book he is cautious about recommending to the private practitioner operations which are really only possible in well-appointed hospitals with skilled assistance. The book is well illustrated and is of interest as an example of the practice in Germany with regard to obstetrical operations.

LIBRARY TABLE

The Buried Temple By MAURICE MAETERLINCK. Translated by ALFRED SUTRO London George Allen. 1902. Pp 276, crown octavo. Price 5*s.*—In this book the author invests with all the charm of his own admirable style the various vague ideas which occur to a brooding mind upon some of the great mysteries of life. The task which he has set himself is eminently a task of criticism. He falls foul of the churches the poets and the philosophers of his time. But the critical faculty is precisely that in which he is wanting In suggestive glimpses of great truths and in convincing statement of what many of us dimly feel to be true Maurice Maeterlinck stands among the great minds not only of his nation but his time, but surefooted criticism is by no means in his way Much of what he says leaves the reader with the impression that he might equally well have said the reverse and all has to be taken upon the authority of his somewhat oracular utterance. How far the author is from that intellectual serenity which is indispensable to the higher work of criticism may be seen at once from his petulant remarks about the Boer war It is not however by such imperfect features of his work that Maeterlinck must be tried, and when he speaks of matters which are truly within his compass he says what is more than notable. For instance the following dictum concerning the use of symbolism in poetry is a sample of much that could be found in these fascinating pages It is time that the poet should realise that the symbol is legitimate only when it stands for accepted truth or for truth which as yet we cannot, or will not, accept, but the symbol is out of place at a time when it is truth itself that we seek. And, besides, to merit admission into a really living poem, the symbol should be at least as great and beautiful as the truth for which it stands, and should, moreover, precede this truth and not follow a long way behind" It remains only to add that the translation has been excellently well done, though for some curious reason here and there the translator uses the auxiliary "will" as a Frenchman or a Scotsman might, meaning thereby "shall."

Letters to Young Wives and Mothers, Nos 1, 2, and 3 By **FREDA LORAINE** London The Cable Printing and Publishing Co, Limited. Price 6*d* each.—These three little pamphlets contain some admirable advice to expectant mothers. Lady Loraine's remarks are shortly summarised by the quotation given at the head of letter 1. "Whatsoever things are pure, whatsoever things are lovely, whatsoever things are of good report Think on these things." There is but little doubt, we think, that a mother's temperament, "conversation," and surroundings during her pregnancy have an influence for good or for evil upon her as yet unborn child. If a woman is during her pregnancy contented, in easy circumstances, and surrounded by beautiful objects her child is much more likely to be healthy, good tempered, and patient of control than if in its prenatal days its mother has been worried, anxious, and bad tempered. Although happiness and contentment are not within the reach of everyone Lady Loraine has done well in pointing out to those chiefly concerned that a mother can exercise an influence over her unborn child, and even the trying to be contented will often result in attainment.

JOURNALS

Medical Magazine—The interest of the July number of the *Medical Magazine* centres in an announcement contained therein which is headed "The *Medical Magazine* and Medical Protection." The magazine is to be supplied to all present and future members of the London and Counties Medical Protection Society and an attempt is to be made by special issues from time to time to "keep the medical profession constantly and systematically in touch with those questions which most vitally affect its own interests and thus to enlist its sympathy and coöperation." We are always in sympathy with efforts aimed at stimulating the interest of medical men in the practical politics of their own profession and shall be glad if the *Medical Magazine* succeeds in this direction.

Journal of Anatomy and Physiology Conducted by Sir **WILLIAM TURNER**, K.C.B. F.R.S., **D. J. CUNNINGHAM**, M.D., F.R.S., **G. S. HUNTINGTON**, M.D., **A. MACALISTER** M.D., F.R.S., and **J. G. M'KENDRICK**, M.D., F.R.S. Vol. XXXVI. New Series, Vol. XVI Part 4 July, 1902. With Plates and Figures in the Text. London Charles Griffin and Co, Limited. 8vo Pp 112. Price 6s Index Number—The following articles are contained in this number of the journal 1. On the Succession and Homologies of the Molar and Pre-molar Teeth in the Mammalia, by H. W. Marett Tims, M.D. Edin 2. The Normal Position of the Big Toe, by Joseph Griffiths, M.D. Edin., F.R.C.S. Eng Dr Griffiths gives drawings and measurements which show that in the newly born child, in the adult, in the savage, as well as in civilised man, both of the present day and as represented to us in Greek sculpture, the big toe is asymmetrical gently curved in its long axis with the convexity inwards towards the opposite foot, and is directed outwards more or less from the inner line of the foot as well as from the line of the innermost metatarsal bone. 3. On two cases of Dental Anomaly, by O. Charnock Bradley, M.B. Edin. One of these cases occurred in the horse and in this there was a supernumerary molar in the maxilla, whilst in the other the premaxillary region of a calf prese[illegible] regards as [illegible] the individu[illegible] of reversion [illegible] plement of [illegible] 4 [illegible] note on the [illegible] [illegible]ion in some Arctoid by R. J. An[illegible], M.D. R.U.I. 5 Two Rare Vertebr Anomalies, by E. Barclay Smith, M.D. Camb. 6. On th Natural Preservation of the Brain in the Ancient Egyptian by G. Elliott Smith, Fellow of St. John's College, Cambridg Professor of Anatomy, Egyptian Government School, o Medicine, Cairo, with a plate. 7 The Primary Sub-division of the Mammalian Cerebellum, by G. Ellio Smith. 8 On the Presence of an Additional Incisor Toot in a Prehistoric Egyptian, by G. Elliott Smith. 9 Not on a Case of Muscular Abnormality observed during Lif by Professor T. Wardrop Griffith, M.D. Aberd The ca appears to be one of complete absence of the stern and of a small part of the clavicular origin of th pectoralis major of the right side in a man. 10 On th Arrangement of the Branches of the Mammalian Aortic Arch by F. G. Parsons, F.R.C.S. Eng Drawings of the norm arrangement of the vessels in many animals are given 11. The Relative Weights of the Right and Left Sides of th Body in the Fœtus, by T. G. Moorhead, M.B. Dub 12. Th Comparative Histology of the Urethra, by J. Strickland Goodall, M.B. Lond. 13. A Supra Clavicularis, Propriu (Gruber), by P. P. Laidlaw, St. John's College, Cambridge 14 Emargination of the Patella, by the Rev F. C. Kempson M.B. Camb In addition to an index to the thirty-sixt volume the part contains the Proceedings of the Anatomica Society of Great Britain and Ireland

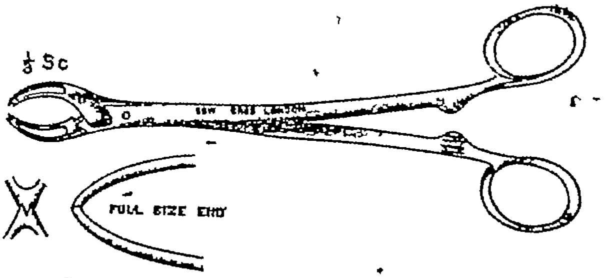
LONG ARTERY FORCEPS FOR DEEP WOUNDS

IT is sometimes rather difficult to place a ligature on a bleeding point in a very deep wound, as, for instance on the pelvic floor in an abdominal section when the abdominal incision is small and the walls are thick, or in a vaginal section when the vessel is almost out of reach. Ordinary artery forceps are too short and in using most long forceps one is apt to include the ends of the blades in tying the ligatures Messrs. Down Bros have made to my design a pair of forceps which are figured here and which seem to render considerable help in the conditions indicated The shaft is nine inches long The instrument bears a superficial resemblance to a large pair of Morrant Baker's artery forceps, but it differs from them in the construction of the blades. These are not serrated but terminate in fine toothed ends. The blades are broadly bowed with somewhat obtuse points. They take up but a small piece of tissue, and a loop of ligature thrown over the shoulder and drawn tight runs well over the ends, and it is almost impossible to tie the extremity of the forceps in the tissue seized The instrument has the shafts, handles, and catch of Morrant Baker's forceps and the blades and toothed ends of ordinary artery forceps, except that its bow is shorter and wider. It has an aseptic joint and weighs two ounces.



Complete forceps with enlarged view of bow and grip

THE LANCET.

LONDON SATURDAY AUGUST 16 1902

The Metropolitan Hospital Sunday Fund for 1902

IF the congregations which assembled in the various places of worship in the metropolis on Hospital Sunday were not equal to the task of raising the Hospital Sunday Fund for 1902 to £80 000 so as to insure with the aid of the munificence of Mr GEORGE HERRING a grand total of £100 000 we may at any rate congratulate them upon a "record" collection wherewith to celebrate the coronation of King EDWARD VII the end of the war in South Africa, and the thirtieth year of the Fund.

In 1873 the Metropolitan Hospital Sunday Fund was inaugurated and in that year it reached £27 700 of which £1844 ranked as donations as distinct from collections obtained in places of worship. This year, as we announced last week in THE LANCET the contributions from places of worship *alone* amounted to £45 000—a sum exceeding nearly all the grand totals of previous years *including* donations In fact, only three times have the grand totals of the Fund exceeded the amount collected this year in the places of worship The grand total also when completed will probably this year exceed that of 1895 when it amounted to £60 361 the highest figure as yet registered. Such a result is satisfactory for while we urged all to contribute upon an unexampled scale, and so to commemorate the great events of a memorable year and although there was much in the declaration of peace and in the approaching coronation of our beloved KING and QUEEN to excite kindly feelings and to stimulate generosity we did not, and do not forget that there were circumstances also to be considered which were likely to diminish rather than to increase the offerings of the majority The year 1895, to which we have referred, was distinguished by a boom in South African mining shares which had a corresponding effect in other markets The late Mr BARNEY BARNATO and his friends contributed £10 000 and the Stock Exchange at large joined the list of donors with £3400 while no doubt other minor givers felt similar impulses towards generosity accompanied by special means to gratify them. This year all the circumstances are entirely different. The country is feeling the effects of a long and costly war the price of most securities is down and the coronation has caused expenses which many have had to take into consideration, and which the untoward illness of the KING has materially increased for many of his subjects. When these things are taken into consideration it will be seen that the Hospital Sunday Fund is to be cordially congratulated upon its thirtieth anniversary, while we may express the hope that years of increased prosperity may be coming and that the forward step now taken may never be retraced.

To THE LANCET the success of the Hospital Sunday Fund is a source of keen gratification. At the time of this year's collection the *Pall Mall Gazette* published an interesting interview with Sir HENRY BURDETT than whom no one is better qualified to speak on every point connected with the financial organisation of our hospitals while all know how much the Hospital Sunday Fund owes to his resource and energy In speaking to his interviewer of the origin of the Hospital Sunday movement Sir HENRY BURDETT described how Sir SYDNEY WATERLOW then Lord Mayor wrote to the Mayor of Birmingham for particulars of the working of the Hospital Sunday movement in his municipality but, he added, the idea had been debated in London before that. Dr WAKLEY a former Editor of THE LANCET for instance, had repeatedly urged upon successive Lord Mayors the necessity of some such scheme. Dr WAKLEY indeed is entitled to claim the paternity of the movement in London. We are particularly gratified at this public acknowledgment of the assistance given to the Fund at its commencement by the late Dr JAMES WAKLEY and trust that it does not savour of family pride if we also allude to the fact that he set the example to private donors of large sums by giving £1000 in 1885 and the same sum in 1886 while his executors in 1887 paid a like amount under his will. These sums in the years named stood alone and the importance of their effect may be judged by examination of the donations of subsequent years among which the gifts of 1895 to which we have already alluded the regular and noble contributions of Sir SAVILE CROSSLEY and the princely generosity of Mr GEORGE HERRING in recent years may be specially referred to

At the meeting of the council of the Fund on August 5th graceful reference was specially made to the efforts of THE LANCET by Mr ALFRED WILLETT in proposing a resolution of thanks to the editors of newspapers who have pleaded the needs of hospitals and advocated the cause of the Metropolitan Hospital Sunday Fund. We appreciate highly such recognition as this of the work that we have endeavoured to do in a good cause, and we shall continue to hope that the annual supplement which we devote to the Fund has some influence in unloosing the purse strings of those who peruse it in their places of worship on Hospital Sunday and elsewhere In the form which it took this year it made the patients in the hospitals themselves the advocates of the hospitals cause and if any of those whose experience in the wards was published by us follow the fortunes of the Fund in the newspapers we hope that it will give them pleasure to see that a record collection has followed the issue of their stories. Those members of the staffs of the hospitals who cooperated in enabling us to prepare the supplement will also we believe enjoy a similar feeling of satisfaction. In fact the steady progress of the Fund is well calculated to be a source of gratification to all those who are labouring to maintain its advance Directly and indirectly the Fund has had a considerable influence on the institutions on whose behalf it was founded and that influence has been wholly for good. We may repeat in conclusion the sincere hope that the splendid collection of 1902 may form part of a continued and well sustained progressive movement and that a substantial increase from year to year may be looked for in the future.

◆

The Simulation of Abdominal Disease by Intra-thoracic Lesions

IN the present state of medical science it may safely be said that in many morbid conditions the art of diagnosis has far outstripped treatment, and we may, indeed, legitimately pride ourselves on the strides which have been made in introducing and perfecting our methods of diagnosis and in enlisting the assistance of various diagnostic aids There is, however, no small danger that we may over-estimate the exactness with which we can recognise a disease and this danger is especially acute in those cases in which diagnosis is rapidly followed by energetic surgical treatment, for it may easily happen that from a slight misreading of the signs that are present the aid of the surgeon is invoked and an operation is performed which was quite unnecessary and therefore, to some extent at least, harmful There is a well known passage in one of GALEN'S works in which he describes how he detected an error of diagnosis on the part of a Sicilian physician at Rome. The Sicilian physician was himself the patient and suffered from a sharp shooting pain in his right hypochondrium A short dry cough also troubled him and his breathing was frequent and shallow and he therefore had diagnosed pleurisy GALEN by the acuteness of his observation was able to show that the real condition from which the patient was suffering was an acute hepatitis. We see, then, that it is not difficult to mistake a morbid condition of an abdominal viscus for a disease of the thorax. At the present time, however, the reverse mistake in diagnosis is much more likely to be made and an intra thoracic affection mistaken for some abdominal disease In hospital practice this is specially prone to occur A patient with marked abdominal symptoms is far more likely to be admitted under the care of a surgeon than to be sent into a medical ward Even in private practice, too, sudden and severe abdominal pain is so suggestive of perforation of a gastric ulcer or of an inflamed appendix that a surgeon is much more likely to be called in than a physician

This is especially the era of exploratory laparotomy We say this with no invidious meaning When marked abdominal symptoms are present, such as pain, distension, tenderness, and vomiting, the surgeon may hesitate to make an exact diagnosis and yet he may reasonably feel justified in saying that some serious abdominal condition is present and that an exploratory laparotomy is advisable not only to establish a diagnosis but to carry out the treatment For in such cases diagnosis and treatment go hand in hand. Experience justifies the confidence that the surgeon feels, for in 99 cases out of 100 these symptoms are to be attributed correctly to abdominal lesion and the laparotomy in revealing the diagnosis shows also how best to treat the condition. But there are exceptions Occasionally, very occasionally indeed, a case is seen in which a superficial or even a fairly thorough examination will suggest that there is some gross abdominal lesion present and yet the cause is seated within the thorax This very important subject has been brought forward by Mr H L BARNARD who has contributed a paper published in THE LANCET of August 2nd, p 280 He has collected six cases in which a morbid condition of the pleura or the lung has led to symptoms suggesting a general peritonitis. Another case of the same kind appears in the Mirror of Hospital Practice in the present number of THE LANCET (p 440) The intra thoracic conditions which have caused these severe abdominal signs are all to be found in the lowest part of the chest, either affecting the pleura where it covers the diaphragm or the inner surface of the chest wall, or the base of the lung itself In all the cases quoted in the paper that we have mentioned the pleura was affected, but in half of the cases there was also a basal pneumonia The symptoms and signs which suggested the abdominal source of the trouble were numerous and Mr BARNARD divides them into parietal and visceral The wall of the abdomen is exceedingly tender, in some cases universally so, but in others the tenderness is limited sometimes to one area, sometimes to another The spasm of the abdominal muscles is well marked and confirms the diagnosis of an abdominal lesion, and this spasm may be so severe as to cause the greatest difficulty in returning into the abdomen any bowel which may have escaped during a laparotomy The breathing is shallow and chiefly thoracic, but there are two points of diagnostic importance in connexion with the respiration. In the first place, at each inspiration there is a momentary relaxation of the spasm of the abdominal muscles This is not the case when the spasm is due to general peritonitis The other valuable diagnostic sign is the greatly increased frequency of the respiration. The signs and symptoms which are visceral in nature are numerous Nausea, hiccough, and vomiting may be very severe and the intestines are much distended Constipation, too, is nearly always present There is also often great collapse With such symptoms is it to be wondered at that an error of diagnosis is made and that these signs are attributed to perforation of some abdominal viscus? Especially excusable would such an error be if some previous symptoms should point in the same direction For instance, in one of Mr BARNARD'S cases there was a history of gastric ulcer, and the patient, a girl aged 17 years, was suddenly seized with violent epigastric pain and vomiting The abdomen was tender, rigid, and distended, especially at the epigastrium A diagnosis of perforating gastric ulcer was obvious and yet this patient was suffering from a double basal pneumonia with diaphragmatic pleurisy on the right side.

The chief danger in the diagnosis consists in preconceived ideas. A surgeon rarely sees cases of pleurisy, he frequently sees cases of peritonitis, and if he, therefore, should be called to a case with the severe abdominal symptoms already mentioned a diagnosis of peritonitis will very likely be made, but he should be on his guard, and a little further examination, a little consideration of the symptoms will make it clear that he is dealing with a case in which thoracic is simulating abdominal disease The extreme rapidity of the respiration without any corresponding increase of the pulse rate points conclusively to pulmonary or pleuritic disease. Further the abdominal tenderness is merely superficial and disappears when firm pressure is exerted and the presence of intra thoracic signs will confirm the suspicion engendered by the examination of the abdomen Should unfortunately the true nature of the case not be recognised and a laparotomy be performed it may be that little direct harm will be done, but in addition to the difficulty of closing the abdominal wound due to the rigidity of the muscles, the risk of septic peritonitis is not absolutely negligible and the depression from the operation, slight though that depression may be, cannot but impair the patient's chance of recovery from severe pneumonia or pleurisy There is, moreover a further danger the anæsthetic may serve to make worse any pulmonary disease present and this is a risk which must not be forgotten The explanation of these abdominal symptoms is to be sought chiefly in the nervous supply of the skin and the viscera of the abdomen. The terminations of the lower dorsal nerves supply the upper abdominal wall, and the pain caused by lesions in structures supplied by one branch is referred to the distribution of another. Mr BARNARD'S paper is well worthy of careful perusal and its importance is great, for on a correct diagnosis much depends.

The Notification of Tuberculosis

THE powerful plea on behalf of the adoption of compulsory notification in cases of phthisis advanced in these columns by Dr BYROM BRAMWELL in a recent series of lectures deserves the earnest consideration of the medical profession. He is not alone in his advocacy of a measure which *primâ facie* would seem to be the logical outcome of the recognition of the infectivity of tuberculosis. In the course of a most interesting debate, which took place in the section of State Medicine during the recent meeting of the British Medical Association and which is reported this week in our columns, some of the best known and most experienced of our medical sanitarians took the view that some form of notification is highly valuable to the community in dealing with tuberculosis. Hitherto it must be confessed the suggestion has not commended itself to the majority of the profession or to those responsible for the administration of the laws relating to public health. We have more than once expressed an adverse opinion, holding that even if desirable it is hardly practicable It seems like one of those "counsels of perfection" which cannot be seriously entertained in the present state of society Dr BRAMWELL and those who think with him entertain the belief that unless compulsory notification be enforced it will not be possible materially to reduce the prevalence of tuberculous diseases but compulsory notification is only of value when supported by other measures the fulfilment of which in the case of so widespread a disease as tuberculosis could only be obtained at enormous cost and after disturbance of social and family relations with the infliction of hardships upon individuals which the inexhaustible fount of charity might be unable to remove Dr BRAMWELL has boldly faced these difficulties and balancing the advantages of the plan against its disadvantages is convinced that it is not only feasible but essential to the subjugation of the disease He does well to point out that the method of dealing with tuberculosis differs from the procedure adopted in the case of acute infectious diseases, although the aim in view is the same—namely to limit the spread of infection. Moreover in tuberculosis the question is a comparatively simple one in so far as the measures of protection are concerned for the infective agency is known, its mode of transmission from sick to healthy fairly obvious It is not here that difficulties arise but in the fact that the disease is endemic and fostered by the conditions of life inseparable from large communities. For this reason the task of combating it on the lines pursued by sanitary authorities in the acute infectious disorders is rendered far more complex and the difficulties of dealing with it becomes well nigh insuperable. To carry out thoroughly the measures necessary to banish tuberculosis means the provision of machinery so extensive as to stagger the imagination. One involuntarily pictures the land covered with sanatoriums and hospital which, like the lazar houses that played so large a part in the subjugation of leprosy would in time to come be no longer required, having done the work for which they were intended. Well may we ask if there is no other way to deal with this scourge and pause before setting on foot a scheme which would have such gigantic issues.

On the other hand, it is idle not to recognise the importance of a knowledge of the prevalence of tuberculosis which a system of registration would supply and the use to which such knowledge may be put in enforcing the laws of health, neglect of which has so much to do with thi prevalence. And the modified plan of notification suggested by Dr BRAMWELL on the basis of that adopted in New York for this disease and in Edinburgh for infectious diseases generally would certainly materially aid the struggle against the disease. For on this plan the medical practitioner himself would take on much of the duty falling to the sanitary authority whose aid he would summon if he deemed fit. He would see that proper means of disinfection were carried out, that the people were instructed in the very simple methods involved in the destruction of sputum and that overcrowding was diminished and the dwelling purified by light and ventilation. The public must be instructed how easily the risks of contamination can be avoided and how low is the infectivity of tubercle in healthy environments. Much, very much can be done in this educational manner and it is to the medical man that the public will look for instruction. But it would surely be disastrous if the idea became prevalent that the phthisical patient was one to be avoided and to be removed without delay as if the disease were as dangerous to others as say small-pox. The fear of infection, which has gained perhaps too great a hold of the public mind has doubtless its good purpose albeit it is making modern man a selfish and pusillanimous creature but in such a disease as tuberculosis there is no room for such a feeling to enter in view of the fact that the infectivity is comparatively slight and the means of protecting against it so simple and easy At the same time it is for our profession never to cease impressing on the public that tuberculosis is curable and that the [illegible] can [illegible] to hand in the [illegible] practice [illegible] of the principles which underlie all sanatorial treatment. By all means let these institutions be multiplied, but let us not forget that the rational treatment of the tuberculous subject does not necessarily imply resort to any institution at all.

And this brings us to the great lesson which modern knowledge of the nature of tuberculosis teaches, which cannot be too strenuously urged upon those responsible for the health of large communities. We have suffered generations to grow up under conditions in which tuberculosis is bound to flourish. The measures which the most active sanitary authority can take under the most perfect system of notification are doomed to failure so long as these conditions prevail. Is it not worth while to consider before entering upon a scheme which will involve such heavy burdens whether a wiser course would not be to set steadily to work at the improvement of dwellings and the establishment on the outskirts of all large towns of "garden cities" which should gradually come to replace the courts and alleys which will always remain as hotbeds of disease? If the adoption of compulsory notification and all that is therein implied would tend to check, or perhaps entirely set aside, the more permanent schemes of prevention we should still decline to believe that it was the best means to eradicate tuberculosis. Dr. BRAMWELL speaks of voluntary notification (which is now being adopted in many centres) as a makeshift, but may not the same term apply to the more extended system if it stand in the way of the thorough and only scheme likely to subdue this scourge of civilisation? The debate in the section of State Medicine during the meeting of the British Medical Association, to which we have already referred, terminated in the unanimous adoption of a motion urging the Local Government Board to grant extended powers for dealing with tuberculosis to local authorities. By all means let these powers be granted, for they would be placed in discreet hands. But the public, instructed by the medical profession, must realise that such proceeding would not minimise their own responsibility the matter. A regulation of a Government department cannot convert an unhealthy city into a healthy one, and the prevention of tuberculosis must be largely a question of sanitation in its broadest sense.

Annotations.

"Ne quid nimis."

THE CORONATION

ON Saturday, August 9th, King Edward VII. and Queen Alexandra were crowned at Westminster Abbey, adding to a long list of memorable coronations one the circumstances of which will never be forgotten by their subjects or by future generations. The postponement of the ceremony and the cause which led to it are matters too recent and too well known for us to dwell upon; it is, however, a matter for profound thankfulness that His Majesty was able to go through such a ceremony without distressing fatigue, and that his exertions should have in no way checked or retarded his progress towards perfect health. The ancient and interesting religious rites and observances had been condensed and curtailed as far as possible with a view to their performance on June 26th, the date originally fixed, so that there was little that could be omitted or abbreviated. The ceremony was by no means a short one, and no better proof of his renewed strength could have been given to His Majesty's subjects, both those who were privileged actually to see him crowned and anointed and those who waited his return from the ceremony wearing the insignia of royalty, than the King's demeanour throughout the day. Not only did His Majesty pass through the midst of his people along an extended route, but he afterwards showed himself upon the balcony of his palace to those assembled to greet him. The weather which prevailed in London on August 9th was unusually cold for the time of year, a fortunate circumstance which must have contributed in no small degree towards enabling the King to endure to the end in comfort and without undue exhaustion. Coronation robes are not garments which even a strong man would lightly undertake to wear and move in during what are known as the dog days, but the grey still weather of last Saturday, while it diminished to some extent the magnificence of the spectacle in the streets, was *ideal from the point of view of all who were not merely* onlookers, and if His Majesty is always favoured throughout his reign with days as suitable to the task which he may have in hand he will be fortunate indeed. To the physicians, surgeons, and nurses to whom the charge of His Majesty during the recent weeks of anxiety was entrusted, and particularly to Sir Frederick Treves who performed the operation, we beg to offer our sincere congratulations. With the eyes not of their countrymen only but of the whole world upon them they have successfully done the duty that was allotted to them and the conclusion at which they aimed they have triumphantly arrived at. To the whole world they have given a striking example of the service which medical science places at the disposal of high and low, rich and poor, saving the life of the mechanic in the hospital without hope of reward or restoring to a people the monarch to whose long reign in health, peace, and prosperity we now look forward. To their Majesties we offer our heartfelt congratulations, joining in the chorus of goodwill which has echoed and re-echoed throughout the world. The warmth of the greeting that would be given to them by their people we were safe in predicting last week, and our prognostication was realised in a magnificent outburst of spontaneous enthusiasm. It was, indeed, a fitting reception for the King and his Royal Consort that the streets of London saw last Saturday, a reception that must for ever assure their Majesties of the place which they occupy in the hearts of their loyal subjects.

THE IMPERIAL VACCINATION LEAGUE

IN our issue of July 5th we referred to the formal constitution of the Imperial Vaccination League and the most important points which the promoters of the league considered should be dealt with. In a letter which was published in the *Times* of August 11th, a letter signed by His Grace the Archbishop of Canterbury, the Bishop of London, and the Duke of Northumberland, Lord Kelvin, Sir William Broadbent, Sir Victor Horsley, Sir W. S. Church, and Dr. J. C. McVail, to quote only a few of the names, the league points out that "It will consider if the entire supply of glycerinated calf lymph should not be guaranteed and regulated by some public authority. In Germany for 55,000,000 people there are 22 state laboratories for the preparation of lymph. In Great Britain and Ireland for 40,000,000 people we have but one. Private practitioners have to trust to the vendors of lymph without any guarantee as to its age or quality. If a central authority for vaccination were established under the Local Government Board the provision of an adequate amount of lymph would be an important part of its duties." It cannot be doubted that the fact of the preparation of vaccine lymph being left to a very large extent in private hands makes for a sad want of uniformity in the quality of lymph supplied This want of uniformity and the defects inseparable from haphazard methods of preparation were well brought out by the results of our Special Commission on Glycerinated Calf Vaccine Lymphs which appeared in THE LANCET[1] and it is quite possible that much of the prejudice against vaccination is due to the use of either impure lymphs which produce various septic troubles or else to the insufficient protection afforded by an inert lymph The great experiment of the Vaccination Act of 1898 comes to an end next year and it would be a useful duty on the part of the League to press the Government to consider the question of revaccination

THE KING'S SANATORIUM THE PRIZE COMPETITION FOR THE ERECTION OF A SANATORIUM IN ENGLAND FOR TUBERCULOSIS

DR. ARTHUR LATHAM'S address on the Modern Treatment of Pulmonary Consumption, which will be found in the columns of our present issue, presents some points of historical interest. It was read before the Hunterian Society of St. George's Hospital on Nov 24th, 1901. Last week we announced that the King had sanctioned the award of three prizes for essays on the subject of sanatoriums for phthisical patients and that Dr Latham had gained the first prize of £500. Dr Latham's prize essay was founded upon the address which we now publish.

A WINTER IN CYPRUS

A MEDICAL correspondent has written to us warmly eulogising the climatic conditions of Cyprus from personal experience and calling attention to its suitability as a health resort. He says that at the commencement of the British occupation the initial blunder of encamping our small army on the salt marshes near Larnaca gave the island a wholly undeserved reputation as a fever stricken place. It is true that fever occurs at certain seasons and within certain limited areas but in winter the coast is *free from it*. From *December to April* last winter reminded him of a long English summer, the average temperature at 9 A M. was 55° F on only two or three evenings did he find it necessary to wear an over coat, and at night his bedroom window was always wide open The rainfall was practically *nil*. Limasol he considers to be probably the best town for winter residence. It has a small English colony and an excellent club and polo, cricket, football, hockey and tennis are played. There is an hotel with good bedrooms but the sanitary arrangements have not yet been brought up to date. In February and March he made a leisurely tour of the island, starting from Limasol with mules, some of which carried the camp and belongings, the retinue consisting of two muleteers and a cook. He camped the first night at Pissouri next day he visited the ruins of the temple of Venus and camped that night at Ktima or New Papho A few nights afterwards he camped at Pyrgo on the sea shore, the water being in fact only 10 feet from the tents. In due course he arrived at Nicosia, the capital and the seat of government, the climate here was bracing being colder than on the coast, but in its way it was just as fine. Nicosia is a typical Eastern town walled, and with fine bazaars An enjoyable stay of a week was made here. The High Commissioner showed much interest in the question of Cyprus as a health resort. There is an excellent hospital, ably administered by Mr R. A. Cleveland Two or three days journey camping at night brought the party to Famagusta, where they camped in a pretty plantation at the gate of a fortress. The magnificent old fortifications give an air of picturesqueness to the place, Othello's tower still stands and the harbour is being developed Passing through Larnaca, where there is a model hospital designed and superintended by Dr G A. Williamson an accomplished bacteriologist, they finally returned to Limasol thereby completing the round of the island. Our correspondent was so pleased with his experiences that he hopes to pay a second visit to Cyprus next winter taking patients with him. He considers that the climate is suitable for a variety of pulmonary complaints, especially in the incipient stage. The chief drawbacks are the limited extent of the available accommodation and the absence of pasturage with the consequent want of fresh milk and butter

THE MEDICAL OFFICER OF THE BALLACHULISH SLATE QUARRIES

MORE than a month has now elapsed since the directors of the Ballachulish slate quarry dismissed Dr L. Grant from his position as medical officer at the quarry but they have not yet given him any satisfactory explanation of their reason for doing so. They have, however presented their own version of the case in a published statement which is to our mind anything rather than a justification of their high handed action and is, in fact, about as lame and feeble an apology as can be imagined. This document, which seems to have been posted up or displayed at the quarry on August 4th was addressed to the men was dated July 26th and began by professing to show something of the rights of the case." It then continues as follows —

> The medical gentleman at Ballachulish has always been a quarry doctor in the first instance, but the country is getting filled, big works are opened up, more people are living around, and of late the quarry doctor it appears to the directors of the company has been inclined to take on work which makes it necessary that he should be more and more absent from the neighbourhood of the quarries and the directors do not like it. When the present gentleman came to Ballachulish he signed an agreement with the directors which agreement either party might end on giving one month's notice Most people stick to a bargain but Dr Grant or more likely injudicious friends have raised a cry of dismissal cruel ill-treatment and so forth and have not put before you the facts of the case fully Have you been told that Dr Grant has put it out of his power to practise in the district on the termination of his engagement and that he has barred himself by law from accepting any appointment from you? If you want to know why the directors are not satisfied with the recent agreement I will inform you that it was not sufficiently binding to prevent Dr Grant from taking work on at a distant granite quarry ...... In conclusion, I must express my great regret that people connected with the quarries have interfered .....

The quarrymen's reply to this communication was that their medical committee met on August 4th and confirmed their appointment of Dr Grant as medical officer for the quarrymen requesting him to be prepared forthwith to give such medical services as might be required by themselves or their families. The medical committee further expressed the opinion (1) that the men had already given the directors sufficient notice of their intention to appoint their own medical officer[1]; and (2) that they were better able to judge of the care and attention paid by him to his duties than was possible for the directors who did not reside in the district. On August 7th a mass meeting of the men was held at which a resolution was adopted protesting against the action of the directors in applying to the courts and seeking to interdict Dr Grant from practising in Ballachulish. Our advice to the quarrymen and to Dr Grant is to adhere to the position which they have taken up The essential weakness of the statement published by the directors is the remark that Dr Grant was more and more absent from the neighbourhood of the quarries and the directors do not like it. That would be all very well if the workers in the quarries were helpless dependents like the coolies employed in coffee plantations and tea gardens, but a Highland quarryman is very unlike an East Indian coolie, and if he strongly approves of the *status in quo* he is not likely to be far wrong The "distant granite quarry," which is said to take Dr Grant too far from the slate quarry, is, we understand, about four and a half miles from his house, from which it is reached by a good road It employs about 60 or 70 men, and, considering the sparseness of the population, it is obvious that the men at the two quarries must be acquaintances The distance between the places would not be reckoned great in that part of the country, and for the directors seriously to put this forward as their reason for dismissing the medical officer would almost lead us to imagine that they were influenced by some other motive which they were unwilling to disclose

ILLNESS FROM THE PATIENT'S POINT OF VIEW

OUR profession is, perhaps, accustomed to look at disease somewhat too exclusively from the point of view of the medical man We are apt to forget that from the patient's side many symptoms wear a very different aspect There are many small contrivances which a patient learns only by experience and which yet serve to mitigate greatly the pain and discomfort of the invalid It would be of interest to gather the experience of medical men on the nursing and general management of illnesses from which they have themselves suffered, for medical men, alas, have no prerogative of immunity from disease In the present number of THE LANCET (see page 455) we publish some suggestions made by a member of our own profession who has suffered for 24 years, and we cannot but think that they may prove helpful to his fellow practitioners

THE PRESIDENTIAL ADDRESS AT THE AMERICAN NEUROLOGICAL ASSOCIATION

IN his presidential address delivered at the recent annual meeting of the American Neurological Association and published in the *Journal of Nervous and Mental Disease* for July last Professor Joseph Collins gives a concise epitome of the most important work that has been done in neurology during the year past Although no epoch making contribution has appeared there was no dearth of effort to solve the many problems in the anatomy and pathology of the nervous system with which we are confronted. The neuron theory which to day stands as the basis of all neurology and neuro-pathology, in spite of criticisms and of the most elaborate histological investigations, has become more firmly established than ever Recent researches notably those of Apáthy and Bethe, were, explains Professor Collins, not in reality in antagonism to the neuron theory All investigation tended to show that "ontogenetically the neurons (or nerve elements) became more intimately united in series and that such intimacy was structually heightened by use." There were, however many obscurities still surrounding the question of the growth of axis cylinders in relation to their cell bodies or trophic centres which required to be cleared up There also remained for solution the question whether in the human cerebral cortex the presence of the dendritic cell-processes and the neuroglia sufficed to account for the relative large separation of the nerve cell bodies, or whether a certain amount of intercellular substance remained which accounted for the appearance in question In the field of cortical localisation the results of Horsley and Beevor as obtained by the methods of local electric stimulation of the cortex in the higher anthropoid apes had been corroborated and expanded by Sherrington and Grünbaum Flechsig in the latest of his wonderful researches on the association centres of the human brain was able to show that from 30 to 40 "areas" or centres could be mapped out on the brain in accordance with their times and rates of development. Important confirmation of the same had come from the researches of Schäffer of Buda pest and Storch of Breslau on general paralysis Much attention had been devoted to the study of tendon reflexes, the most important and valuable discovery in this direction being the so called Babinski reflex, which is now accepted as a definite indication of degeneration of the pyramidal tract The subjects of "toxæmia" and of "internal secretion" were receiving more attention, and further investigations in these directions were needed to elucidate the pathology of exophthalmic goitre, acromegaly, and allied disorders Quite recently Professor Mills of Philadelphia had shown that the Roentgen rays were of use in determining the site and occurrence of certain kinds of cerebral tumours Dr Henry Head had published a suggestive report upon visceral disease and the mental changes accompanying them, and there was still great room for the further investigation of such neuroses as hysteria neurasthenia and hypochondriasis in which mental disorders co existed On the whole, concludes Professor Collins, there has been more than usual activity in the realms of neurology and questions of the vastest importance were still awaiting solution

THE RECEPTION OF DEAD BODIES AT HOSPITALS

AN inquest was recently held at the London Hospital by Mr Wynne E Baxter on the body of a female child, aged about 14 days, of unknown parentage It was stated in evidence that the child was brought in after death had taken place by a woman who stated that the child had been treated at the hospital on the previous day The cause of death was found to be bronchitis The woman gave a name and address but the information was found to be false Some of the members of the jury made remarks which we consider not only uncalled for but showing ignorance of the responsibilities which the resident medical officers should or should not take upon themselves Dead bodies are frequently brought to the hospitals and the medical officer on duty having obtained the name and address of the deceased and of those bringing the body, and having made inquiries as to the nature of the illness or accident which was supposed to have caused death, has discharged his duties satisfactorily It would be on very rare occasions that he would be justified in detaining persons who had brought in the dead body and calling the police. The position of the medical officer is strictly that of a medical man and not that of a detective

THE RESULTS OF A VOLCANIC ERUPTION

AT a recent meeting of the French Academy of Medicine M Kermorgant gave some details taken from reports of the colonial medical officers of the condition in which the victims of the St. Pierre catastrophe were found In the centre of the town there had apparently been the most violent explosion. Bodies were found shattered to pieces or with several fractures in the arms and legs In many cases the skulls were broken to pieces and empty Further away from the centre of the town bodies were found lying exactly as they had fallen at the moment of death and these were in great part carbonised Death appears to have occurred either from the inhalation of gases at an extremely high temperature which had brought about sudden coagulation of the blood or from electric shock Those persons who had not been killed instantaneously must have had terrible difficulty in breathing The nose was generally full of dust and fragments of pumice The pharynx and the larynx showed traces of burning as low down as the bronchi. In some instances portions of mucous membrane had sloughed.

These details are full of interest and appear to justify what we wrote in our issue of May 17th that it is, however some consolation to reflect that the wholesale destruction of human life by rivers of molten lava deluging a town or by the incessant hail of hot sulphurous cinders filling the air does not necessarily imply an agonising death On the contrary it is probable that, in some instances at any rate, there is no struggle—the vapours of lava would quickly overpower and render the victims senseless and in this state they would probably be overcome by asphyxiation and die." In the same article we remarked that it was reported that many of the bodies presented the appearance of having been struck by lightning

CHOLERA IN EGYPT

THE following figures show the distribution of cholera throughout Egypt for the week ending August 4th The total number of cases was 346, of which 185 were new cases. The total number of deaths was 278, of recoveries 13, and 109 cases remained *under treatment*. The *Director-General* of the Sanitary Department reports that he is glad to be able to state that the diminution in the number of cases reported from Cairo last week continues, and it is to be hoped that the epidemic in this city will take no further very serious proportions. The disease is spreading somewhat in the vicinity of Assiout. The report continues —

> During the week Abou Tig Deirout, Mellawi Beni Masoud and Beba have declared cases but in none of the towns up to the present has the disease shown any tendency to spread in an alarming manner *It is much to be hoped that we have succeeded in finding the first* cases early and so shall be able by vigorous measures to prevent the spread of the disease in these towns, but I fear it must be expected for some time to come that we shall hear of fresh towns becoming infected from time to time. A marked improvement has taken place at Mouchs during the last few days. The Sanitary Commission of Cairo has recommended the permanent closure of all wells in Cairo the water of which is considered contaminated by leakage from cesspools, &c. This measure which is in my opinion, of the greatest importance not only for the prevention of the spread of cholera during the present epidemic but also for the prevention of so much enteric fever in the town which no doubt is due in a great measure to the consumption of water from polluted wells will be taken in hand at once. In all towns infected special hospitals have been established for the reception of patients and all possible measures taken to prevent the spread of the disease.

SYNTHETIC SILK.

SYNTHETICS loom large even now although it is true that attention has chiefly been turned to the synthesis of drugs. But there is no reason why equal success should not attend the efforts of the chemist to build up articles of food, drink, and clothing from their elements in the same way as mere chemical compounds have been constructed. It is only a question of the growth of knowledge of the constitution of matter Already the *synthesis* of many articles of common daily occurrence has been effected. The aniline colouring matters are practically synthetics indigo and madder are common products of the laboratory and sugar and alcohol may be prepared from the elements which compose them. The latest achievement of the building chemist appears to be the artificial production of at any rate the most important constituent of silk. Chemists have long known that the chief constituent of silk—insects cocoons and spiders threads—is an insoluble proteid, behaving very much in the same way as proteids in general of which the albumins are types Mulberry silk in particular consists of over 70 per cent. of a proteid substance termed fibroin associated with 22 per cent. of a *yellowish* transparent substance resembling gelatin in composition and character and known as sericin. These two albuminous substances occur in silk with about 3 per cent. of wax and 1 per cent of mineral matter It is sericin however or rather its derivative by hydrolysis serine, which has been successfully synthesised, and inasmuch as silk owes its peculiar and delightful character largely to this substance there is no doubt that an important step towards the artificial manufacture of silk has been made. Day by day synthetics are forcing themselves upon *our* notice and are threatening to take a place somewhere or other in man s ordinary routine. The question has still to be settled whether a synthetically or artificially prepared substance—that is, one which is identical as far as can be judged with the natural product—gives precisely the same satisfactory results. Most people, we are sure will confess so far to a sneaking preference for the thing which nature takes time to elaborate rather than for the product conjured up so to speak, in a few hours in the laboratory But already it is getting difficult in some directions to obtain the natural article. It is so, at any rate, with indigo, and it is just possible that in the near future it will be no uncommon experience to hear in the shops a customer precise in his demand for either the synthetic or natural article in accordance with his choice. It is to be feared, however *that as synthetic successes are scored so fresh room* for fraud will be opened and this fact is quite sufficient to raise a prejudice in the meantime.

A NEW PATHOLOGICAL SCHOLARSHIP

IT was mentioned at the meeting of the British Medical Association recently held at Manchester that Mr J Francis Mason of Freeland Lodge Woodstock, Oxfordshire has through Dr T F S Caverhill of Edinburgh, offered a scholarship *of £200* a year with *extension to two or* three years if the work seems to promise good results for the purpose of carrying on investigation into the physiology and pathology of the thymus gland including if necessary collateral investigations on the other ductless glands. The founder of the scholarship has associated with himself Dr Caverhill and Professor G Sims Woodhead to act as a small committee for the purpose of selecting a suitable candidate. In filling up the scholarship preference will be given to those who have already made a study of the thymus or other ductless glands, or have given some evidence of their fitness to carry on this or similar work, and who will devote the whole of their time during their tenure of the scholarship to the special research mentioned Every facility for carrying on this work in the Pathological Laboratories, Cambridge, will be placed at the disposal of the scholar *and farther particulars will be found* in our advertisement columns

HYPOPLASIA OF THE AORTA

IT more than occasionally happens that morbid conditions of rare occurrence are shown to exist more *frequently than* was previously imagined. This may be explained partly by improved methods of examination (e.g actinomycosis) or because, attention having been drawn to one or two instances, certain observers keep close watch on all cases likely to prove of the same nature. In a communication which we published in THE LANCET of August 9th p. 358, Dr W Lee Dickinson records four cases of hypoplasia of the aorta—a condition which has not been generally recognisable on account of its rarity As Dr Dickinson points out the cases he records having occurred within 10 years in the experience of a single hospital suggest that the association of aortic hypoplasia and aneurysm should be worth *looking for* in the future, especially perhaps in those cases of aneurysm which are least susceptible of explanation by ordinary causes such as aneurysms in women and young children. Women are notoriously more liable to hypoplasia than men and the suggestion presents itself that some degree of hypoplasia not necessarily to be seen unless searched for may be the reason for the more untoward course of their aneurysms Dr Dickinson further mentions the connexion alleged to exist between arterial hypoplasia and hæmophilia, a disease which modern clinical pathology has proved to depend essentially upon deficient coagulability of the blood. He adds that although hypoplasia does not always, or even generally, imply hæmophilia it at least constitutes an ominous link between aneurysm and the possibility of an undesirable condition of the blood. This suggestion may have an important bearing on the treatment of aneurysm and must certainly be taken into account when forming a prognosis. Dr Dickinson has done good service in drawing attention to a condition that has been but little studied

THE RECENT EPIDEMIC OF SMALL-POX IN GLASGOW

IN the year 1896 five cases of small-pox occurred in Glasgow In 1897 there were 59 cases, but from the early winter of that year until March, 1900, the city appeared to be quite free from the disease, except for one patient who was admitted into hospital on June 5th, 1899, having apparently fallen a victim from exposure to infection in Marseilles On March 18th, 1900, a steamer arrived at Glasgow from Bombay *viâ* Liverpool, at which latter port small pox was found to be on board , the crew were therefore kept under medical observation during the time that the vessel lay at Glasgow—namely, from March 18th to 21st. On April 10th Dr A K. Chalmers, medical officer of health of Glasgow, was asked to see a case of illness in an over crowded one-apartment house, No 3, Tobago-street, in the central sanitary district of the city The patient was one of the crew of the steamer in question. He had been reported to Dr Chalmers as having gone away on board the vessel on March 21st, and he had in fact signed the ship's articles for the outgoing voyage, but he remained on shore at the time of sailing , he was now near the end of the second week of an attack of confluent small pox, and he soon died , no medical aid had been obtained until April 9th It was a considerable time since any tenement in the city had been exposed to such concentrated and continued infection as this, and by April 23rd it was found that 11 other cases had originated from this man's illness The disease thus casually introduced has continued to exist until practically the present time with periods of greater or less prevalence and an interval of more than three months—namely, from the middle of July to the beginning of November, 1901, during which it seemed to be absent From the commencement of the outbreak in April, 1900, to the end of that year there were 397 cases or an average of about 10 per week, but during the fortnight ended Jan. 26th, 1901, there occurred 350 cases and the numbers for each of the four next fortnights were successively 202, 127, 299, and 161. The total for the year 1901 was 1399 The number of cases from the beginning of 1902 up to May 3rd was 459 As already mentioned there was an interrupted continuance of small pox from April, 1900, to July, 1901. In his voluminous report on this formidable outbreak Dr Chalmers classifies this epoch as the "pre-epidemic and epidemic periods" During this time there occurred 1759 cases, in only 10 of which the patients were not removed to hospital, the attacks having ended in death or recovery at home before their nature was recognised. There were 234 deaths As the accepted number of the population is 761,712 these figures represent an attack rate for the whole population of 2 3 per 1000, a death rate of 0 3 per 1000, and a case mortality of 13 3 per cent. His detailed statistics repeat and emphasise what has been common knowledge as to the protective power of vaccination Another interesting section of his report describes the measures taken for the promotion of revaccination among the general public. When the outbreak had been about two months in progress—namely, in June, 1900—he was authorised by the health committee to issue a circular to the medical profession urging the desirability of general revaccination and offering them a fee of 1*s* 6*d* for each successful revaccination of persons over 10 years of age and unable to pay for the operation There were 964 revaccinations performed by practitioners in terms of this circular, and at the same time about 7000 revaccinations were performed by officials of the health department When the epidemic increased greatly in January, 1901, a fresh circular was issued offering a fee of 1*s* 6*d* for revaccinations of persons over five years of age and withdrawing the stipulation regarding their inability to pay fees. The age limit was reduced to five years because of the number of children admitted with trifling vaccination cicatrices Dr Chalmers says "The immediate result of these was to convert the consulting rooms of practitioners in infected districts into vaccination stations, where the work of revaccination went on frequently for hours daily" The recurring increase in the number of admissions to hospital early in March led to the adoption of a system of house to house visitation, and a circular was issued to practitioners offering a fee of 2*s* 6*d* for vaccinations so obtained. The summary of the revaccinations done by the officers of the sanitary department and by practitioners during 1901 was as follows —At office, 486, in hospitals, 556 , at residence, by staff of department, 14,763 ; in prisons and poorhouses, 11,293 , by practitioners, in terms of circular letter of Jan. 24th in 1901, 283,423 , by special vaccinators working in enumeration districts, 29,081 , by practitioners in enumeration districts, in terms of circular letter of March 7th in 1901, 12,424 , total, 352,026 The number of tubes of glycerinated calf lymph issued to practitioners in the first four months of 1901 was as follows in January, 18,141 , in February, 37,143 , in March, 39,737 , and in April, 1706 From June 1st, 1900, to March 1st, 1902, the amount expended in connexion with revaccination was as follows calf lymph, £4570 , fees to practitioners, £22,776 , fees to extra vaccination staff, &c , £4177 , fees to prison and parish surgeons, £713 , total, £32,236 The justification of this outlay is to be found in the fact that no case of small pox occurred in a person recently revaccinated prior to exposure to infection , there were, however, 126 cases of the well-known condition of concurrent variola and vaccinia, showing that revaccination had been performed subsequently to exposure to small-pox infection—i.e , after the disease had been already contracted. A very important and instructive section of Dr Chalmers's report is that in which he discusses the dissemination of small pox and comes to the conclusion that a hospital for the disease may become a source of infection for the neighbourhood. Nearly 20 years ago Mr W H. Power, the present medical officer of the Local Government Board conducted a similar inquiry and came to a similar conclusion with respect to the small-pox hospital at Fulham in the west of London, and we have recently published articles making like allegations against the small pox ships moored in the Thames opposite Purfleet.[1]

CANCER RESEARCH FUND

THE Executive Committee of the Cancer Research Fund has decided, as may have been seen by reference to our advertisement columns last week, to appoint a general superintendent to supervise the investigation into the causes, prevention, and treatment of cancer The duties of the office will include (1) the general direction of laboratory investigation , (2) the supervision of workers appointed by or receiving grants from the committee , (3) the collection of statistical, dietetic, topographical, and other information , (4) the organisation of a system of correspondence with colonial,

---

[1] THE LANCET Jan 25th (p 273), Feb 22nd (pp 495 and 534), and April 26th (p 1172), 1902.

Indian, and foreign laboratories and workers and (5) attendance at the meetings of the Executive Committee or any committee appointed by them for special purposes relating to the investigation. *The general superintendent may also be* appointed director of the central laboratory For further information reference should be made to the Secretary Examination Hall Victoria Embankment, London, W C. to whom applications must be sent before Oct. 1st It is the intention of the Executive Committee to make appointments early in that month when a serious start to carry out the objects of the fund will be made.

THE DISTRIBUTION OF PLAGUE

THE weekly return of the Director General of the Sanitary Department in Egypt shows that for the week ending August 3rd there were 3 new cases admitted all of which occurred in natives. The deaths numbered 2, the recoveries 9 and 13 cases remained under treatment. With respect to sanitary measures 18,775 rooms were disinfected and 504 were lime-washed 78 sacks of effects were disinfected and 1761 sacks of rubbish were burnt. The number of rats killed and burned was 1128. As regards the Mauritius a telegram from the Governor received at the Colonial Office on August 12th states that for the week ending August 9th there were 2 cases of plague of which 1 was fatal. As regards Hong Kong a telegram from the officer administering the Government received at the Colonial Office on *August 12th, states that for the week ending August 9th* there were 14 cases and 13 deaths.

A CONGRESS OF GYNÆCOLOGY AND OBSTETRICS IN ROME

A Congress of Gynæcology and Obstetrics will be held in Rome on Sept. 15th and following days. The Secretary General to the congress is Dr Ernesto Pestalozza, director of the Maternity Hospital at Florence. The payment of 25 lire (about £1) ensures membership to a duly qualified medical man and railway rates to members of the congress producing their tickets will be reduced by one half In connexion with this congress we are asked to announce that British physicians and surgeons who propose going to Italy will be made very welcome at Salsomaggiore if they desire to visit the place and will communicate with the thermal establishments. A supplementary ticket to Salsomaggiore from Spezzia or Borgo will be presented to them About Sept 11th a commemoration monument to Edoardo Porro the well known obstetrician, will be unveiled at Salsomaggiore a ceremony at which British gynæcologists may like to be present.

THE LIFE HISTORY OF FILARIA BANCROFTI AND FILARIA IMMITIS

IN another column we publish a paper by Dr Louis W Sambon entitled Remarks on the *Life-History* of Filaria Bancrofti and Filaria Immitis." Dr Sambon criticises a paper by Dr Giovanni Noè in which the last named authority strives to prove that the filaria immitis is introduced into the human body by means of mosquito bites, attempting to combat what he terms Dr Patrick Manson's suggestion that infection can take place through ingestion. In our opinion Dr Sambon's is a well reasoned and destructive criticism He clearly proves the fallacies of Dr Noè's experiments pointing out that his observations are unsatisfactory and his conclusions ill founded. He contrasts Dr Noè's rashness with the caution of Dr Manson who having made a special study of filaria for upwards of 20 years, expressed himself with the utmost caution as to the manner in which human beings are infected. Dr Sambon's paper affords interesting *reading* further observations must be made before the analogy of malarial infection can be established with regard to the filaria immitis.

DISCREDIT TO WHOM DISCREDIT IS DUE

IN the daily papers last week the death of a lady was reported under the far too familiar heading ' Fatal Cycle *Accident*." According to the evidence at the inquest the deceased who was 84 years of age was crossing the street near the Army and Navy Stores Westminster when she was knocked down, sustaining a fracture of the femur which subsequently proved fatal. A witness who was not contradicted, said that the unfortunate lady was alongside his bicycle when a cab in front of him suddenly turned round forcing the machine against her He did all that was possible to avoid an accident but could not. The verdict of the coroner's jury was ' Accidental death. Some days later in Kensington High street, a gentleman met with his death while riding *in a trailer* which was attached to a motor-cycle driven by his brother A van in front suddenly turned into Warwick road the result being a collision during which the deceased was thrown violently from his seat, sustaining a fracture of the skull with other injuries which led to his death. The man who was driving the van stated that before he turned into Warwick road out of the main thoroughfare he gave due warning by waving his whip but the rider of the cycle contested this, asserting positively that no recognisable signal was made. In this case also the verdict was 'Accidental death. *The deplorably long list of accidents* in which *cycles* are *concerned* is *not due so much to reckless* or furious riding on the part of the cyclists as to carelessness and indifference on the part of the drivers of vehicles The latter very often turn down side streets or even completely round in the same street without looking behind them or warning the after-comers of their intentions. Primarily of course, it is the duty of a driver to look where he is going but the present state of urban traffic makes it necessary that he should on occasion take a more comprehensive survey The construction of many vans which are permitted to ply in crowded places is certainly conducive to *negligence on* the part of apathetic drivers—a view to the rear and even in some cases sideways, being only obtainable at the expense of personal inconvenience. The unstable cyclist being so often a helpless factor in the causation of street accidents *it certainly does seem unfair that he should* be compelled to wipe up as they say in France, the whole of the discredit. But the crowded streets of cities are not suitable for bicycles.

LOST FINGER-TIPS RESTORED BY "SPONGE EDUCTION

I *American Medicine* of July 26th Dr George E. Abbott of Pasadena, California describes two cases in each of which, after the tip of the right index finger had been crushed off he succeeded in bringing about an elongation of the *stump to the* extent of at least half an inch. In the first case the portion of the nail left after the accident measured only one-sixteenth of an inch. After two or three days the skin began to close in and round over the top of the finger Dr Abbott then *commenced treatment by* sponge eduction ' leading on the granulations by means of a sponge graft so placed that the granulations of the pulp would grow onward and guiding those of the skin until it was time for them to bend round the point of the finger The result was that the finger became quite half an inch longer than it would have been had it been allowed to heal in the usual manner a well shaped nail was formed, and there was in fact no disfigurement whatever The second patient came under treatment two weeks after the accident. Dr Abbott found that more than half an inch of the right index finger had been crushed off The entire nail and apparently all of the matrix were crushed , there was no nail whatsoever, a little callous ridge alone showing an abortive attempt to redevelop the nail , the stump had completely healed except at the extremity where there was a mass of exuberant granulations about an eighth of an inch in diameter The same treatment was followed as in the previous case, with the result that the finger was advanced fully half an inch Photo prints of the restored fingers accompany the article The operations were performed as follows The patient having been anæsthetised a straight incision was made from side to side through the stump, just as a knife would be passed under the matrix and root of the nail had it been in place This gave one straight flap on the back of the finger in which the nail was to develop, in the event of any part of the matrix being still in a living condition The end of the stump was then incised into four triangular shaped flaps having their apices at the centre of the nail flap and their bases at the circumference of the stump These were then dissected up so that when the finger was held upright they formed a crown around the stump except at the back, which was occupied by the matrix flap Into this crown, in close contact with the denuded end of the finger, was placed the sponge graft into which the granulations were to grow The sponge was held in place by adhesive plaster, bandaged with gauze , it was kept constantly wet with warm normal salt solution. The sponge in place) was syringed every day with a solution consisting of one part pyrozone (a solution of peroxide of hydrogen), one part saturated solution of boric acid, and two parts of sterilised warm water Every three days the adhesive strips and the old sponge were removed and replaced by new Sponge grafts for surface work and eduction sponges (mastoid shaped portions used to stimulate granulations for filling up cavities) must be made of fine grained, stiff sponge, not of coarse, soft, open sponge , it is essential that the sponge should be cut transversely to its pores or tubes

"OPENINGS FOR BEGINNERS"

It has been represented to us by an energetic medical society in the suburbs of London that advertisements, very generally headed "Opening for medical practitioner" or "Suitable to a medical man beginning practice," are extremely misleading in character It is seldom that an advertisement of this sort gets into the columns of The Lancet In most cases these advertisements are simply part of an agent s or auctioneer's scheme to get rid of a house and the opening exists only in the tradesman's imagination. The medical man, who is always asked a higher rent than other people because of the alleged advantages of the house, generally finds that he cannot support himself in the neighbourhood and leaves within a few weeks, forfeiting perhaps a year's rent. We therefore give this word of warning to our readers

THE PREVALENCE OF SMALL-POX

The following figures show the number of patients admitted to the various hospitals of the Metropolitan Asylums Board for the dates mentioned. On Sunday, August 10th, there was 1 fresh case , on Monday, the 11th, there were 3 fresh cases , on Tuesday, the 12th, there were 5 fresh cases , and on Wednesday, the 13th, there was 1 fresh case

The authorities of the Cancer Hospital, Brompton, have entirely re organised their pathological department and a new laboratory is being fitted up with all requisite appliances for research A pathologist is to be appointed to work in conjunction with, and under the direction of, Mr H. G Plimmer who has been pathologist for many years to the institution and who will now become director

His Majesty the King on August 12th visited the Museum of the Royal College of Surgeons of England accompanied by Sir Frederick Treves The visit was quite private.

Looking Back.

FROM

THE LANCET, *SATURDAY, AUGUST 14*, 1824.

PHARMACEUTICAL CHEMISTRY

Digitaline

M. Augustus Le Royer lately read to the Society of Physics and Natural History of Geneva the following paper,[1] on the active principle contained in the digitalis purpurea (foxglove)

In separating, by skilful analysis, the active principles of different medicinal substances, M. Pelletier has conferred on science the most important service. The use of these new substances becomes every day more familiar to practitioners. They find in them the double advantage of being able to administer in very small doses a powerful medicine, with the quality of which they are accurately acquainted. Those who direct their attention more particularly to the subject of materia medica, could however occupy their time better than in following the steps of this eminent chemist, viz. by analysing those plants which have hitherto escaped M Pelletier's notice Under this impression, I undertook the analysis of the digitalis purpurea, or foxglove, of which I subjoin the principal results

Preparation—I took a pound of the digitalis purpurea, such as you buy in the shops, and treated it in the following manner first, with cold ether, then by this same agent warm, in a retort, so as to be able to elevate the temperature , the liquids thus obtained, after they had been filtered, were of a yellowish green colour, and a bitter taste , the residue, from their evaporation, had a resinous appearance, and an intolerably bitter taste, and which gave to the tongue the same sensation of numbness as is excited in biting the wolf's bane This residue, exposed to the air, rapidly attracted the moisture It became divided into two parts when mixed with distilled water One of these was kept in solution , the other was precipitated, and presented all the appearances of *chlorophyle* , it was not however pure, but still retained some traces of the bitter matter, which could not be removed entirely, even by repeated ablutions with warm water The watery solution of the etherized residue turned yellow litmus paper red I added to it some hydrate of the protoxide of lead, to neutralise the disengaged acid contained in it. The salt of lead which was produced was soluble and could not therefore be separated from the bitter principle , those which the addition of some earths formed could not be separated either, and I was obliged to have recourse to some other means. I evaporated then to dryness the portion combined with the lead, and mixed it with pure rectified ether The result of this operation was, that I obtained in solution in the ether, the active principle of the digitalis, disengaged from the substances with which it was in combination , and subsequent evaporation furnished me with a brown ponderous substance, gradually changing to a blue colour the yellow paper previously reddened by an acid. This last character, together with its bitter qualities, approximated it to the vegetable alkalis , from which, however, its extreme liquefaction separated it This last property prevented it from crystallizing in a distinct and permanent manner , it can nevertheless be ascertained, by the aid of a microscope, that it crystallizes in direct prisms, with rhomboidal bases

PURULENT OPHTHALMIA.

This disease, which is an inflammation of the eyes, attended with a profuse discharge of purulent matter, is at the present time very prevalent in London It is of an exceedingly contagious nature, and those individuals who have the care of schools, or of large establishments, should be particularly cautious to prevent the propagation of the complaint, by not allowing the diseased persons to be placed in immediate contact with the healthy, whether by sleeping in the same beds, or by using the same towels.

---

[1] The excerpt comprises an extract from the paper

THE KING'S CORONATION GIFT

ON August 11th His Majesty the King received in audience the Right Hon. Sir Joseph Dimsdale Bart. M P Lord Mayor of London the Viscount Duncannon, C.V O C B and Sir Savile Crossley Bart M P M V O who presented the Coronation Gift of £115,000 subscribed by all classes of His Majesty's subjects including nearly 20 000 donations in pence given by working people, and who informed His Majesty that there would be a substantial balance on the closing of the accounts, and that increased support had also been secured by King Edward's Hospital Fund for London, the Hospital Sunday Fund and the Hospital Saturday Fund in his coronation year

His Majesty the King in graciously receiving the gift expressed in most feeling and sympathetic terms the pleasure which he experienced in the fact that this tribute embraced the offerings of the poorer classes of his subjects equally with those of the richer His Majesty further conveyed the great gratification he felt that in this year such considerable progress had been made towards the attainment of the object which he had in view when in celebration of the Diamond Jubilee of his beloved mother Queen Victoria, he originated the Fund, in which Her late Majesty took so keen and so sincere an interest The aim of that Fund was to free the London hospitals from debt an end which until it was finally accomplished he should not cease to strive after while God spared his life The King then handed the Coronation Gift to His Royal Highness the Prince of Wales President of King Edward's Hospital Fund for London to the augmentation of which he desired it to be applied

A PATIENT'S SUGGESTIONS

BY W

IT has occurred to me that papers written by patients themselves upon points which occur to them as the most practical and important for their comfort and treatment would be a very valuable addition to the literature of treatment. Moreover I think that there are very few patients who would not be glad of the opportunity of doing some good to those who may be suffering like themselves.

The following notes have been put together as they have occurred to me and without any strict attention to the natural sequence of the principles of treatment and with the idea of arranging them in some more definite order when they are completed but when will that be? Medical men nurses and attendants will probably find some such notes of value and patients themselves may be the gainers by them Moreover it may suggest to other patients some new ideas and very likely improvements upon those that are put down in these papers I have been inclined to work back from the present condition of my illness as it is more easy to set down any notes or suggestions for the treatment of the present than to carry one's mind back to any time in the past

My present condition on which these notes have been based.—There is almost complete loss of power in the voluntary muscles but without pain. There is inability to walk but I am able to stand when the knees are prevented from bending and when I am balanced by some helper for a few seconds I am unable to use my hands for writing but the arms can be raised slightly by means of the deltoid, especially when gaping The appetite is satisfactory My hearing is excellent. My sight has decidedly improved since 1878. There is loss of power in the external rectus muscle of the right eye. This was the first symptom of my illness in 1878.

Clothing.—It is of the greatest importance to keep warm The clothes should be very loose and comfortable. The best overcoat is an ulster so made as to be thrown over the back. The sleeves should be separate and buttoned on to the overcoat after it has been put on An elastic band to keep the cape from flying about is useful My overcoat was made by a local tailor One waistcoat I had made to button at the side but this was not found to be of any advantage. The hat in winter time should have ear flaps. The indoor cap should be very light, but especially it should have protection for the back of the neck. The boots should be very easy, gaiters are a great advantage in summer and in winter Fur lined boots are especially good for winter and patent leather slippers for summer I have found that gloves in winter are best when made without fingers like a fisherman's gloves. A separate cape is very useful in the bath-chair Mits are very useful Silk mits next to the skin are most comfortable

Food.—The greatest advantage is found when the food is administered in small quantities at a time but frequently Food should be cut very fine and minced especially when the teeth have become defective. Soup bovril and meat lozenges I have found very useful particularly when wanting a pick me up but soups are inclined to upset the digestion especially when taken without solid Milk in the form of boiled milk and water (equal parts) can be taken without the patient getting tired of it. A little whisky with it seems to make it more digestible Of stimulants I have taken whisky half an ounce twice a day with milk and two teaspoonfuls with tea. Wine has never seemed to sustain me, but produces a reaction soon after it is taken Tea at breakfast has been most pleasant and cocoa in the simplest forms is useful in cold weather coffee seems irritating Occasionally during the day a small piece of stick chocolate has been pleasant.

Occupation.—Frequent change of occupation has been found best. Generally from a quarter to half an hour has proved enough for any one subject. The morning is given to the more solid work. It is important to find some steady occupation such as reviewing taking the weather, reading solid literature, or writing letters by deputy The afternoon is given to seeing friends and generally about from a quarter to half an hour is enough for each one Later in the afternoon I have solid reading The evening I devote to light literature game or music. It is important to get out into the fresh air every day and the best time is between 12 noon and 1.30 P M The bath chair is very useful for visiting places and people but it is often found tiring I have found sitting out in a house chair in the sun always most restful especially when some one reads to me

Movement.—Frequent change of position is most important. When sitting in a chair I have my position changed often. When I am lying in bed I am rolled over now and then so as to get pressure on different points, no part should be pressed on too long For this purpose the draw sheet is of great importance. By means of this it is easy for anyone nursing to turn the heaviest patient When sitting in a chair a horseshoe water cushion is much the most comfortable The best chair for allowing movement is one which I have had made from a French pattern with many of my own improvements. This chair allows of the back being moved up and down and the foot-board also.

Change.—One of the most important things as I have just said in securing a patient's comfort when he is unable to move is to change his position frequently, whether sitting or lying and also to give him a change of mental occupation and observation. Reading should not be continued too long on any one subject generally from a quarter to half an hour is enough and then a change should be made Similarly a short visit from friends is better than a long one but this of course varies with the character of the visitor When the conversation is "all ends" it is very tiring Too much questioning also is bad for it tires a patient when he has to do all the talking Deaf visitors should be avoided Change of scene is advisable The windows should be low so that the patient may look out There should be either a good distant view or the possibility of seeing many passers-by There is also nothing better than the chance of making observations on the weather To show that frequent change is advisable I here give an outline of one day's doings A M —7 30 A cup of tea is brought to my room. 8 15 I am washed by a man servant I am moved off the bed and put into a chair for breakfast in my bedroom 9 30 I am moved to the commode 10 0 I am put on the bed lying on the right side. 10 30 I am moved off the bed again and dressed using a "castor" chair—i e a chair with very good castors for moving about 11 0 I am put into a (wheeled) house chair taken into the dining room where I look over letters and have answers written till noon. 12 0 I am moved into the bath chair and taken out for an hour P M —1 15 I am placed in an arm chair for lunch. 2 10 I am put into a house chair and taken into the bedroom I rest on the left side with a light behind me so as to enable me to read, I generally sleep for the first half-hour but remain on the bed resting for two hours in all. 4 30 I get up and am placed in a house chair and moved into another room for tea and company 6 to 6 45 I am read to or I look over papers 6 45 I am moved to the bedroom, prepared for dinner, and brought back to the dining-room and placed in an arm chair for dinner 7 30 I am moved on to the sofa, resting on my left side, and I listen to reading or join in games or talk or listen to music 9 0 I am moved into the wheeled chair and taken to the bed room and I undress. I am placed on the left side with my head and shoulders well supported and am careful to avoid any pressure against any bony points It is necessary to be adjusted carefully until I am quite comfortable

Medicine —First night, nothing Second night, "A.B N" pill (one and a half grains of extract of socotrine aloes, one-eighth of a grain of extract of belladonna, and half a grain of extract of nux vomica) This had to be changed because the nux vomica produced a good deal of vesical irritation. Third night, pill of colocynth and hyoscyamus (two and a half grains) I use hot water every morning as an enema. Occasionally tablets of bismuth are taken at night. I take peppermint lozenges during the day when a stimulant is wanted or very occasionally I have half an ounce of brandy Fruit takes the place of aperient medicine, especially if eaten at breakfast Stewed fruit at night is useful but this has a tendency to nauseate after a time. On the evening before taking the aperient I have found it advisable to finish my supper with a pinch of salt.

Sleep —I never take medicines for the purpose of procuring sleep The healthiest method of procuring sleep is mental occupation in the evening and an absence of worry If I lie awake at night I have found a panacea in repeating three or four Latin verses, and before this has been done three times I am asleep In the afternoon almost always sleep comes for half an hour when I am resting after dinner

Rest —See daily *rota* I rest in the afternoon from 2 30 to 4 30 o'clock. I go to bed at 9 P M and rest till 8 30 A.M Frequent change gives most rest. Often when feeling tired in the morning getting up and dressing seem to give me a feeling of restfulness

Micturition —I am thankful to say that I have never had any real difficulty with this The amount of urine varies with the amount of fluid taken and the heat of the weather Milk is much less irritating than anything else. If the milk is taken hot with boiling water (equal parts) it acts as a useful stimulant. In cold weather I find it more digestible and comforting if the milk and water are taken with half an ounce of whisky at meals In the earlier period of my illness the urine was inclined to be rather more irritating, probably from less care being taken as to diet. Sherry is certainly irritating, but this I have not taken for some years It is most important to empty the bladder thoroughly This is effected by careful position, a horseshoe shaped water cushion and an absence of impatience. Concentration of one's attention is advisable Biting a biscuit is often more efficacious in starting water than is drinking fluid A circular cushion was found to interfere with the flow My impatience once led me to percuss frequently over the region of the bladder The result was cystitis and considerable difficulty which lasted for about three or four weeks, and for a long time the cause of this was not recognised. A soft rubber catheter and plenty of oil relieved the difficulty and after this more care was taken as to liquids Barley water at night has been found very beneficial In the arrangements for the day care must be taken to ensure regularity in emptying the bladder At night a bed urinal is left in position Always lying upon one side is preferable to lying on the back and the bed urinal is easily arranged. Sometimes when there is danger of involuntary micturition the flow is prevented by my being made to lean forward by cushion at the back.

Action of the bowels —As every morning I am obliged to use hot water and an enema I may recommend what I have found most useful I now use an alpha enema, which is worked by a nurse or attendant and sends in the water steadily At first I used a folding cistern enema which I could work myself while sitting on the commode A very excellent bedroom commode is one with a cistern of water attached to it, which is worked by the plug handle It all closes conveniently for travelling and the arms of it form a great feature. Now I use it without the cistern.

Some curious points —I find that when I lie upon my left shoulder and let anything press against a point somewhere about the middle of the spine of the scapula I get a curious screwing feeling in that arm, apparently from the contraction of the deltoid and other muscles This is followed by troublesome palpitation and great uneasiness When I am lying down on the sofa and press with my shoulder against anything hard a numbness occurs in my hand and I feel considerable restlessness When I take too much fluid at night and apparently the stomach is distended palpitation follows until either the water passes into the bowel or flatus passes I always lie on my left side with a tendency to be on my back. When the left leg "jumps" I know that it is the stomach that is at fault, when the right leg "jumps" I know that the rectum is the cause of the trouble and that relief will come when the flatus passes. Occasionally I have lost sight of half an object and this is relieved by not using my eyes for from a quarter to half an hour, this is generally connected with some stomach disturbance

METROPOLITAN HOSPITAL SUNDAY FUND

THE following is a list of the awards recommended by the Distribution Committee of the Metropolitan Hospital Sunday Fund for the year 1902 —

GENERAL HOSPITALS

Charing Cross Hospital £1207 10*s* French Hospital, £306 13*s* 4*d* German Hospital, £594 3*s* 4*d*, Great Northern Central Hospital, £1054 3*s* 4*d* Guy's Hospital, £2875 Hampstead Hospital £239 11*s* 8*d*, Italian Hospital, £115 King's College Hospital, £1437 10*s* London Hospital £6181 5*s*, London Homœopathic Hospital, £527 1*s* 8*d*, Phillips Memorial Homœopathic Hospital, £34 10*s* London Temperance Hospital, £776 5*s* Metropolitan Hospital £862 10*s* Mildmay Hospital £287 10*s*, Miller Hospital and Royal Kent Dispensary, £287 10*s* North West London Hospital, £431 5*s* Poplar Hospital £622 18*s* 4*d*, Queen's Jubilee Hospital £95 16*s* 8d Royal Free Hospital £1245 16*s* 8*d* St George's Hospital, £1916 13*s* 4*d* S S John and Elizabeth Hospital £143 15*s* St Mary's Hospital £2491 13*s* 4*d* St. Thomas's Hospital, £1341 13*s* 4*d* Seamen's Hospital Society £1293 15*s* The Middlesex Hospital £2309 11*s* 8*d*. Tottenham Hospital, £383 6*s* 8*d* University College Hospital £1303 6*s* 8*d* Walthamstow, £105 8*s* 4*d* West Ham Hospital, £527 1*s* 8*d*, West London Hospital £814 11*s* 8*d* Westminster Hospital, £1389 11*s* 8*d*.

CHEST HOSPITALS

City of London Hospital for Diseases of the Chest, Victoria park £958 6*s* 8*d*, Hospital for Consumption Brompton, £1820 16*s* 8*d* Mount Vernon Consumption Hospital Hampstead, £670 16*s* 8*d*, Royal Hospital for Diseases of the Chest City road £383 6*s* 6*d* Royal National Hospital for Consumption (Ventnor) £383 6*s* 8*d*

CHILDREN'S HOSPITALS

Alexandra Hospital for Hip Disease W C £239 11*s* 8*d* Banstead Surgical Home £23 19*s* 2*d*. Barnet Home Hospital £43 2*s* 6*d* Belgrave Hospital for Children S W £124 11*s* 8*d* Cheyne Hospital for Incurable Children S W £124 11*s* 8*d* East London Hospital for Children Shadwell, E £766 13*s* 4*d* Evelina Hospital for Sick Children Southwark S.E £287 10*s* Home for Incurable Children Maida Vale W £76 13*s* 4*d* Home for Sick Children Sydenham S E £134 3*s* 4*d*, Hospital for Sick Children Great Ormond street W C £1054 2*s* 4*d*, North Eastern Hospital for Children, Hackney road N E £287 10*s* Paddington-green Hospital for Children W, £297 1*s* 8*d* St Mary's Plaistow E £249 8*s* 4*d* St. Monica's Brondesbury N W, £95 16*s* 8*d* Victoria Hospital for Children King's road, Chelsea, S W £460 Victoria Home, Margate £47 18*s* 4*d* The Vine Sevenoaks, £43 2*s* 8*d*

LYING IN HOSPITALS

British Lying in Hospital Endell street W C, £28 15*s* Clapham Maternity Hospital £38 6*s* 8*d* East-End Mothers Home £76 13*s* 4*d* General Lying in Hospital Lambeth, S E £57 10*s*; Queen Charlotte's Lying in Hospital, Marylebone-road W, £479 3*s* 4*d*

HOSPITALS FOR WOMEN

Chelsea Hospital for Women S W £421 13*s* 4*d* Hospital for Women Soho-square W, £143 15*s* Grosvenor Hospital for Women and Children Vincent-square S W £172 10*s* New Hospital for Women Euston road W C £306 13*s* 4*d* Royal Hospital for Children and Women Lambeth S E, £268 6*s* 8*d* Samaritan Free Hospital, Marylebone-road, W, £492 6*s* 8*d*

OTHER SPECIAL HOSPITALS

Cancer Hospital Brompton, S W, £527 1*s* 8*d* London Fever Hospital Islington N £718 15*s* Gordon Hospital for Fistula Vauxhall bridge-road, S W £23 19*s* 2*d* St Mark's Hospital for Fistula City road E C £143 15*s* National Hospital for the Diseases of the Heart Soho-square W, £76 13*s* 4*d* Female Lock Hospital Harrow road W £306 13*s* 4*d* Hospital for Epilepsy Paralysis and other Diseases of the Nervous System Regent's park N W, £47 18*s* 4*d*. THE BRITISH MEDICAL ASSOCIATION

MEETING AT MANCHESTER.

THE SECTIONS

SURGERY

Friday August 1st

Mr. P J Freyer (London) opened a discussion on

Total Extirpation of the Prostate

One year ago he had published four cases of total extirpation of the prostate with its capsule by a new suprapubic method. A further series of 10 cases, making 14 in all, had been published only the week before The whole of the cases had been absolutely satisfactory save one in which death had occurred on the twenty fourth day from acute mania. He had now seven more cases to report, with a death in one on the ninth day from sudden syncope after having progressed perfectly favourably up to that date He referred in detail to each of the cases, and the parts removed from the whole series of 21 cases were presented to the section For purposes of description he divided the specimens of excised enlarged prostate into three classes (1) those in which the lateral lobes had separated along the superior commissure only the prostate coming away entire and leaving the urethra, and probably in most cases the ejaculatory ducts intact, (2) those in which the lateral lobes had separated along both their superior and inferior commissures and had been removed separately leaving the urethra and the ejaculatory ducts uninjured and (3) *those in which the lobes had not separated along either* commissure the prostate being removed as a whole after the urethra and the ejaculatory ducts had been torn across, and in some instances the prostatic urethra within either partially or entirely removed It would be found in most cases of this type that the prostate was encircled by a thin girdle of fibrous and muscular tissue part of the prostatic sheath so that in these not only had the prostate in its capsule been removed but in addition an actual layer of the sheath had come away

Professor S. Alexander (New York) wished to draw attention to three points. First as to what was the true capsule of the prostate secondly as to what parts of the prostate caused obstruction and thirdly as to the important and marked distinction there was between the lateral lobes of the prostate and that part which was to be found below and behind the seminal ducts. The true capsule of the prostate was that which embraced the whole of the prostatic tissue and was derived from the fibrous pelvic fascia. By a series of beautiful photographs of transverse and sagittal sections of the enlarged prostate he demonstrated very clearly the extent of its sheath showing that it was wanting on the bladder side. Within this true capsule could be seen the lateral lobes, surrounded by a special envelope of their own. As to what parts of the prostate caused obstruction it was essential to recognise that the enlargement was entirely in that part above the urethra, and never in the portion in front of the seminal ducts. The urethra was thus always depressed and the larger the prostate the greater the depression. The anatomical distinction of that portion of the enlarged prostate lying below and behind the seminal ducts from that lying above the urethra was important for this former part never caused obstruction the so-called middle lobe being in reality always an outgrowth of a lateral lobe but it was that part of the prostate liable to carcinoma. He was a strong advocate of the perineal route for removal of the prostate.
